I will be posting some links about sky wire antennas.

If you have any info or links about skywires, please feel free to post them.

Thanks.

Ron,

thanks for joining. I don't have much experiance with Antennas in general, but I'm trying to learn, like you. I'm sure someone here will be able to field your question.

From what I have read, that higher is always better, but a skywire loop is much more forgiving than most when it comes to height.

As far as lightning, Any conductive object will attract lightning. If you are only six foot off the ground, I don't think you have much to worry about, unless lightning happens to hit one of the trees its anchored to, then its anybodys guess as to what will happen.

also, I think you live only about 40 miles from me. (alton, illinois).

keep in touch and let us know how it does.

PS, have you been able to pick up any of the international beacons with your skywire?
http://www.ncdxf.org/beacon/beaconSchedule.html

these are all on CW band, and not AM.

please let us know how they come in. I can generally pick up two or three at any given time, but I don't have my skywire up yet..

thanks.

I have my current antenna (a dipole) run by the slingshot method. are you familiar with it?

It brought my dipole up to about 35 feet, without me having to leave the ground, and only costs a few cents per line.

thanks.

From: exemptfromlife
Topic: 9 Message: 10

This is a odd statement in this article about Art Bell's Skywire Loop Antenna.

He claims it generating 350 volts, and shocks him. I would assume in that dry desert that its a due to blowing sand particles, but I have no idea. I'm sure its not Little green men or some cosmic force, does anybody want to take a guess?

thanks.

Topic: 9 Message: 12

I have heard of people being prosecuted for theft, by laying metal conductors across their property right under high power transmission lines that run across their property. The metal conductors drain some power off of the high voltage lines even though they never touch them. (I've been told this, but don't know if its just an urban legend or not)..

If so, and Art has his SkyWire built in a 360 around his house, perhaps he is siphoning off some of his own electricity from his house.

My first bet would be its because of the dry nature of where he is, and even if the wind isn't blowing, there is enough dust particles in the air to cause some sort of static build up when they hit the wire.

I keep reading about people having wire antennas who during a snow storm see sparks arcing off of their coax wire..

Just wondering

Thanks.

16. Re: Hook up wire VS RU8 coaxial cable

Yahoo group: SkyWires
Date: 2003-09-08 03:58:25 UTC
From: Bill Krause
Topic: 14 Message: 16

This may sound like a pretty silly basic question but I am quiteserious about it. Just hooked up an ICOM PCR1000 and plan on setting up a Ten-tec R320-D in the next couple of days. For the short term I am going to use 40-50 feet of bare copper wire strung accoss the top of the room in a rough square as a temporary antenna , to be followed by a slinky, to be followed by a dipole with traps. The question is how much of a difference in reception will it make if I use insulated hookup wire as my feed from the antenna to the radio comparred to if I use shielded coaxial cable like RU58. This refers only to the temporary indoor long wire and the mobile slinky. Using shielded coax with the dipole is a given.Will I really be able to hear a lot more shortwave stations by using the the RU58??

Bill Krause

Bill,

thanks for posting. I am just starting out in radios/shortwave, etc. I have PCR100 (like a PCR1000). I was using my wire dipole I have outside as its antenna.

I would assume, and maybe some others can comment on this, but I would think that most of the difference is going to come from the interference you would get from electrical wiring, and appliances inside your house.

Re: Hook up wire VS RU8 coaxial cable

BK,

Well basically you have a square flat Horizontal 40-50 Foot Indoor Loop Antenna with a short 8 foot vertical lead-in wire.

An your "Question" is Hook-Up Wire -vice- RG8 Coax Cable ?

1. Simple and Cheap: Hook-Up Wire could be used as the vertical downlead-in wire by starting at the Ceiling Level and 'twisting' the Hook-up Wire together as a pair for the 8 Feet from the Loop Antenna to the Radio. [A Twisted Pair of Lead-in Wires Aids in the 'reducetion' of Noise Pick-Up.) The Ends of the Twisted Pair of wires would connect to the HI-Z Terminals of he radio.
- - - A single roll of RadioShack 20-24 AWG Stranded Wire can be used to make the conplete Loop Antenna and Twisted Pair Lead-in Wire all in one piece. Use 4-5 Plastic Coated Cup-Hooks to hold the Hook-Up Wire Up in Place. (One in Each Corner and One for the Down Lead Position.)

2. Complex and More Costly: An 8 Foot piece of RG8 Coax Cable with a PL-259 Plug on one end; could be used as the vertical down lead-in wire by using a Balun between the Loop Antenna and the Coax Cable. Then routing the Coax Cable to the radio's LO-Z SO-239 Jack.
- - - Requires Roll of Hook-Up Wire; Balun and RG8 Cable with PL-259 Plug.

3. Something Else To Consider (Third Option)
An 8 Foot piece of TV 75 Ohm Coax Cable with "F" Connectors on both ends as the vertical down lead-in wire. Use a TV 300>75 Ohm Matching Transformer as a 'balun' between the Loop Antenna and the Coax Cable.
* Option A: Then routing the Coax Cable to the radio's LO-Z SO-239 Jack and use a "F" Connector to PL-259 Plug Adapter to make the 'connection'.
* Option B: Then routing the Coax Cable to the radio's HI-Z Terminals and 'use' a TV 75>300 Ohm Matching Transformer with the Coax Calbes "F" Connector to connect to the HI-Z Terminals.
- - - Sort of between #1 and #2 in ease and complexity.

NOTE: Even with Indoor Antennas a 'good' Ground may 'improve' reception.

CAUTION: A 'good' Ground Wire Connection to the Radio/Antenna System is Always Required for 'proper' Personal and Electrical Safety.

iane ~ RHF

Howdy,
I have an 80 m loop...100 ft x 3 sided triangle...Top at 80 ft and the base is at 20 ft. Could not find enough points to get it all horizontal. Anyway, I love it and am planing some more big wires in the future.
Just wanted to say howdy and thanks for the invite.

21. Low noise matching xformer for skywire loop

Yahoo group: SkyWires
Date: 2003-09-08 19:46:07 UTC
From: lowalacrity
Topic: 21 Message: 21

Greetings all, Glad to see this group is also taking off well. I posted this message on SWL-AM-FM before i noticed this group. Been building small loops for a couple of years now but decided to try a biggin. I live on a 1/3 acre lot and have tolerant neighbors. I strung about 400ft of 16 around my back yard and house with the start and end winding up where my beverage transformer is mounted. hem... Idea! disconnected the long wire from the primary (35 turns) wound on an Amidon FT-50-42 toroid core. I connected the loop instead. Wonder if a variable resistor from one side to ground would help? The secondary is wound with 11 turns of RG-58/U using a Faraday shielding technique. The center conductor from the end of the winding is soldered to the shield at the start of the winding. A ground wire is also soldered to that joint. Ran the RG-58 straight into my shop. Preliminary results have been positive, low freqs especially. I'm using a DX-394 and have noticed a gain of no less than 2 "S" units improvement on most bands, (compared to an 85 ft longwire). The noise reduction is substantial also! P.S. I gleened the info for my beverage from J. Carr's article in Pop Electronics Jan. 98. I will post a pic of the xformer, (along with legit pics of my home builts that start with trueloop). I'll call this one loopmatcher... http://photos.groups.yahoo.com/group/loopantennas/lst

I am new to this group, i find these sky wires and info quite interesting, also i am anew ham but have not been on the air as of now. The biggest antenna i saw when i wa stationed in Thailand with the air force during the vietnam war, was at NOON SOON Thailand a place called Ramsun station 7rrs radio relay station, this antenna was like astadium round and covered up many acres, i really dont no what went on at this sight most of it was top secret, i figured they monitered the air waves and messages coming out of N Vietnam , China, and any place else in South East Asia, i have apicture of the antenna if i can find it i will post it in the photo alblum.--------Richard in North West Ohio

Rich,

Welcome to the group. The USAF Thai antenna sounds pretty cool.

The biggest I ever saw was when I was a kid, I visited my aunt's farm in Ohio, and the property next door housed the VOA antenna. It looked like three large High power lines towers with a mess of wire between each. Pretty cool to look at when you were 12 years old.

thanks.

I would post one but, because of its size, it would have to be
an "aerial" shot... (pun intended) Maybe i could climb on the roof to
grab one. The shingles are getting pretty shakey though...
A lot of traipsing around in the last 18 years. My whole spread is
one big farm. 3 long wires, multiple loops. (mostly portables). Oh,
and one understanding wife!

Bill,

thanks for posting. I am just starting out in radios/shortwave, etc.
I have PCR100 (like a PCR1000). I was using my wire dipole I have
outside as its antenna.

I would assume, and maybe some others can comment on this, but I
would think that most of the difference is going to come from the
interference you would get from electrical wiring, and appliances
inside your house.

I believe the question is: "will a piece of coax cable 8' to 10' long connecting a wire antenna located in the same room with your computer etal. improve reception". The answer is no doubt NO. In the business of receiving weak signals it is the signal to noise ratio that is important (for really strong stations it doesn't matter anyway). In this scenario the short piece of coax will in effect simply be 8' to 10' more of wire antenna.

You may change the overall signal strength (by chance) but not the S/N ratio. Now if you were talking about a magnetic loop antenna the story is more complicated and the S/N ratio

can indeed be improved (even though the overall signal strength is decreased substantially). The improvement comes from the reduction of noise.

Jim,
Thanks, following this thread along how far away does the copper wire have to be from these sorces of noise for there to be an appreciable improvement in the signal to noise ratio??, would ten or fifteen feet in another room make an appreciable difference?? Would you gain more in moveing the ten or fifteen feet away then you would loose as a result of the longer feed in line?? Thanks for all the help folks.

37. Slingshot method for hanging SkyWires.

Yahoo group: SkyWires

From: exemptfromlife
Topic: 37 Message: 37

Slingshot method for hanging SkyWires.

Guys,

In my youth (19 years old), fresh out of Marine Corps Boot Camp, I would climb to the tops of trees like a monkey, while friends on the ground would yell "that's high enough!!" to put up Owl Nesting boxes, etc.. What they didn't know was it was much easier that most of the stuff the Corps had me doing.

That was then and this is now. Now Walter no longer leaves the ground unless I have a boarding pass, and a coach ticket.

After reading a few articles I decided to try the slingshot method of hanging a wire antenna.

Its Pretty easy.

You need the following items.

A fishing pole, a dozen 1 oz. Lead egg sinkers, a good Crossman or Wrist-Rocket slingshot, a large spool of Trout Line, Large Nails, a hammer, and a Fishing pole holder, if you can't find someone to help.

I've seen ads in radio magazines for a slingshot-fishing reel combo, for $100. If you have $100 to blow, take you wife out to a fancy restaurant. I believe it's a much better investment that this. The slingshot, and a fishing rod and reel will set you back about $30..

I use trout line because it is very strong, and given its to be used in water, its waterproof, and seems to hold up very well, and is cheap. But if someone knows of another rope that works better, please let me know.

You can find all of this at your local bait and tackle store. I pay about 20 cents for each egg sinker, I use egg sinkers because they are about as aerodynamic as fishing weights get, and because the shape doesn't allow them to get hung up in the tree branches as much as others do, but it still happens.

I have heard of people using a Bow and Arrow. I can see some advantage to this, but I think the risks outweigh the benefits. With a 1 oz. Egg sinker, you have to be careful it doesn't come down on a parked car's windshield, or dent the hood. With an Arrow, it could put a hole in someone's roof, or worse, if you neighbor or his kids are outside, they could end up impaled and looking like Gregory Peck in the last scene of the movie "The Omen". We don't want that

When shooting the egg sinker, you want to be on the "Antenna side" of the tree.

Take the pole holder, and place it in the ground at an angle, facing the target tree. Put the fishing pole in the holder.

I have read that if you paint the egg sinkers blaze orange, you can see them better when they come down. I haven't tried this, but it makes sense. Having a florescent fishing line in your fishing reel helps in locating the downed egg sinker, but is not necessary.

If you are right handed, taking the slingshot in the left hand, and stand with the fishing pole to the right of you. If left handed, do the opposite. Place the egg sinker in the sling with the fishing line coming out of the top, and clear from the rubber bands.

Make sure not to stand too close to the tree, you want the egg sinker to clear the tree, and fall on the far side, if you are too close, you will be shooting at too high an angle and the egg sinker won't fall on the far side, but on the shooting side.

Shoot the egg sinker and pay attention to the direction of where you shoot, and see if you can judge where it should have landed before you walk over to the far side of the tree.

Then go find it. You may find that you need to take the fishing pole and "play" with the line a bit to get the egg sinker to fall down to ground level from the higher branches.

If it gets hung up, you will just have to reel it back and start over. I have about a 50/50 success rate.

Once I find the egg sinker, I cut it off, then tie the trout line to it and go back to the fishing pole and reel the trout line back over the top of the tree.

When the trout line reaches the pole, cut the line, and tie your dog bone insulator on to it.

Go back and cut the trout line from the trout line spool, and take two large nails and hammer each of them about half way into the trunk of the tree. The nails should be about a foot or so apart and angled away from each other forming a cleat.

I like to hammer the nails high enough that some kids don't come along and decide to undo my work. If this is a real concern, you may consider using a ladder and nail them higher up on the trunk of the tree. Plus, the higher up, generally the less visible it is too.

Tie the trout line around one nail.

Repeat these steps on all the trees in your SkyWire system.

Once you run your antenna wire through the dog bone insulator you can then begin to raise the antenna by taking the slack out of the trout line. Just begin wrapping the trout line around the both nails in a loop until the antenna reaches the desired height.

That's about it.

I am currently working on a fuse system that uses a bungee cord, and counter-weight, so that when bad weather hits, and high winds put too much pressure on the SkyWire, that the "fuse" will break
causing
about 20 feet of extra trout line to be unleashed, and letting the SkyWire fall limp, but not letting it break. This would allow you to easily recover the extra trout line, and put a new "fuse"
back into
the system after the storm passes.

Once I have the dynamics of this worked out, I will post it.
(sometime this fall, I hope)..

Thanks,

Walter

I've used the slingshot method with the cord placed neatly on the ground so it will feed.... Needless to say, you'll find out just how rough the ground is where you are if you do this. It's even worse if you're off the lawn and in "the rough".. Using a fishing pole and reel to feed the line is a good way to improve the method, but I figured, why not go all the way and dispense with the slingshot altogether? Besides, I had more than a few "misfires" with the slingshot from not placing the weight in just the right place in the pocket...

Having remembered the early days of fishing as a youth, and visualizing the many casts that seemed to go nearly straight up, only to come down a paltry twenty or thirty feet in front of me with a very loud plop, I figured a decent weight and a salt-water fishing pole with spinning reel would be the ticket.

Well, using a one or two ounce weight, it is definitely possible to get the weight over most trees, and with fewer tries than the typical slingshot (which tends to be very picky about where you put the weight in the pouch, among other things...) Just cast over the tree, attach a stronger pull line or wire to the fishing line in place of the weight, and reel away. Continue to the next tree and repeat until you are ready to put tension on the wire antenna. With this method, if you are putting up a skywire, you need to go past the tree and cast towards the last tree/support, working your way out. It seems a bit backwards at first, but works quite well once you get used to it.

Good Luck!
-_Rick

I am going to hook an outdoor sloping dipole to it. Plan to order one
from Universial in the next few days. Down the road maybe a fan dipole
of my own creation, but I still would like a good indoor antenna for it.
Is this realisticly possible??

Hi Bill:

First question about how far from noise sources to make an improvement: well within the house the various areas where the noise is loudest and where it is the quietest is really a matter of trial and error. You can go around and check the noise sources within your house and try to deal with them in one way or another. However, the sources may not be within your house but your house wiring etc may be involved with carrying the noise. I heard one person on Yahoo describe how he used an external type active antenna to place it in different locations until he found the best spot. It is one of those active antennas that contain the amplifier and whip in a small box which connects back to the control box with a length of coax cable. They were originally designed to be mounted outside and the cable to be routed in to the listening location. However he didn't mount his outside just walked it around inside his house to find the best spot and apparently experienced good improvement in reception.

You asked about signal loss due to the length of the coax. Not a major consideration in reception, certainly not at HF frequencies. Most receivers have more than enough gain to overcome losses. In reception on LF, MW, and HF the key is the signal to noise ratio. This ratio is almost always improved by noise reduction techniques rather than signal gain.

Most people think they cannot put an antenna outside the house because it is too large and will violate some zoning law etc.... I believe it is more important that the antenna be outside the house to avoid the noise that permeates the house rather than to make a large antenna. If you have any kind of yard outside the house you have the making of a good receiving antenna.

For example: you may have a small back yard with some wood fencing. You can staple some thin unobtrusive wire along the wood fence (any length will do) and bring it down to ground level (stapled to a fence pole). Run some thin coax from your house (eg from a basement window) like tv coax or RG 174 etc.. to the fence post (make a simple slit in the grass and push the

coax in. Connect the wire to the coax with a small simple RF transformer (you can make your own for a few dollars). No one will see such an antenna and I guarantee it will do a better job than anything you can provide inside the house. If the wire on the fence is only 8' - 10' long you may need a pre-amplifier near the receiver to amplify the signal. However the S/N ratio will be much better and reception far superior to any kind of wire inside the house.

The example I gave above is primarily for reception on HF .... eg 1.8-30 MHTZ. For MW reception you can greatly improve your reception using tuned loop antennas in the house as a tool to reduce noise and other interference and improve reception.

Each situation is different. The best way to get a sense of how far away from your building the interference radiates is with a portable radio. Tune to a frequency where the noise is obvious and walk around with the radio. In my situation about 10 feet begins to help a lot. Even the far side of the deck brings an appreciable improvement on some frequencies.

Hi Bill:

First question about how far from noise sources to make an improvement: well within the house the various areas where the noise is loudest and where it is the quietest is really a matter of trial and error. You can go around and check the noise sources within your house and try to deal with them in one way or another. However, the sources may not be within your house but your house wiring etc may be involved with carrying the noise. I heard one person on Yahoo describe how he used an external type active antenna to place it in different locations until he found the best spot. It is one of those active antennas that contain the amplifier and whip in a small box which connects back to the control box with a length of coax cable. They were originally designed to be mounted outside and the cable to be routed in to the listening location. However he didn't mount his outside just walked it around inside his house to find the best spot and apparently experienced good improvement in reception.

You asked about signal loss due to the length of the coax. Not a major consideration in reception, certainly not at HF frequencies. Most receivers have more than enough gain to overcome losses. In reception on LF, MW, and HF the key is the signal to noise ratio. This ratio is almost always improved by noise reduction techniques rather than signal gain.

Most people think they cannot put an antenna outside the house because it is too large and will violate some zoning law etc.... I believe it is more important that the antenna be outside the house to avoid the noise that permeates the house rather than to make a large antenna. If you have any

kind of yard outside the house you have the making of a good receiving antenna.

For example: you may have a small back yard with some wood fencing. You can staple some thin unobtrusive wire along the wood fence (any length will do) and bring it down to ground level (stapled to a fence pole). Run some thin coax from your house (eg from a basement window) like tv coax or RG 174 etc.. to the fence post (make a simple slit in the grass and push the coax in. Connect the wire to the coax with a small simple RF transformer (you can make your own for a few dollars). No one will see such an antenna and I guarantee it will do a better job than anything you can provide inside the house. If the wire on the fence is only 8' - 10' long you may need a pre-amplifier near the receiver to amplify the signal. However the S/N ratio will be much better and reception far superior to any kind of wire inside the house.

The example I gave above is primarily for reception on HF .... eg 1.8-30 MHTZ. For MW reception you can greatly improve your reception using tuned loop antennas in the house as a tool to reduce noise and other interference and improve reception.

Jay,

The small portable radio "Sniffer" trick works well for finding the good RF 'Quiet Shots' and those bad RFI/EMF "Hot Spots" inside the house/building too. The 'right' location of your radio inside house can solve many man made noise problems.

Hold a small portable radio next to a Dimmer Switch, Touch-Lite or old Computer Monitor: Tell the Better-Half that this is generating more Cancer 'causing' RFI/EMF then her Celphone and she will drive you Home Depot/Lowes/CompUSA to get the things fixed :o)

44. 80 meter loop for all hf bands

Yahoo group: SkyWires
Date: 2003-09-12 01:40:38 UTC
From: w_r_adams1
Topic: 44 Message: 44

L. B. Cebik's antenna site has a great discussion of the "Loop SkyWire" for each of the HF ham bands. The URL is http://www.cebik.com/hl.html
As I believe someone has mentioned, the QST article that intoduced the name is available to ARRL members at http://www.arrl.org/members-only/tis/info/pdf/8511020.pdf

While browsing the ARRL site, I noticed an 80 meter dx version of the loop at http://www.arrl.org/members-only/tis/info/pdf/0208030.pdf

Bill

Thanks for posting this.

He said that this is a "model" does he mean that this is what an antenna software prediction program said would happen, or did I mis-understand?

thanks.

Yes the analysis is based on computer modeling of the antenna. For the assumed antenna size, configuration, height and ground condition, the model presents calculated vertical and horizontal patterns at various HF frequencies.

One of the results is that there is a lobe on the side of the loop away from the feed. I wish I had the room and trees to actually build a version with an ability to switch feeds from corner to corner.

Jim and others thanks very much for all the help. You have given me a lot of ideas and information to work with and try some things out. I have outdoor antenna on the way and it should be up and running within a week. I also plan on at least one or possibly two more outdoor antennas. I also plan on continuing to work on indoor rigs. I am particularly interested in developing something I can take with me when I travel to setup either in a motel room or outdoors at a camp site.

50. Slopper Dipole

Yahoo group: SkyWires
Date: 2003-09-14 14:54:55 UTC
From: Bill Krause
Topic: 50 Message: 50

A crazy question What makes a slopper a slopper other than how it is installed??. It is really any different than any other dipole with tuned traps?? What would happen if I installed it with only a very shallow angle??

Bill

BK,

FLAT - First lets consider the Normal "Flat" Dipole.
= = = Plain Wire Antenna Elements (No-Traps).
* That is 'mounted' Flat-Horizontal.
* Cut for a specific frequency band
* Directional (Figure Eight)
* Optimum 'mounting' Height Half-Wave Length to a Wave Length above the ground surface or more for a true free air antenna.
* NOTE: A 'good' ground is not required for a properly "Elevated" Dipole Antenna.
* * A Dipole Antenna at the 'right' Height, that is only 'off' horizontal by 15 Degrees or less is still basically a Flat Dipole.

TILTED - Next what type of so called "SLOPPER" Dipole are you talking about ?
= = = Plain Wire Antenna Elements (No-Traps).
* A Tip-to-Tip (Top to Bottom) Slopper that is simply "Tilted" in One Direction. [The "T2FD" is he more common Slopper Dipole.]
* A Tip-Center-Tip (Bottom-Top-Bottom) (Dual Slopper) which is commonly called an Inverted "V" Dipole Antenna.
* NOTE: Both of these antennas make use of the ground proximity to add loading capacitance and to some degree achieve both a broader frequency band useage and redued directivity.
* These two antennas require a good ground for their best performance.
* * A "Tilted" Dipole or Inverted "V" Dipole who's elements are Slanted by 30 degrees or more; with an 'average height of about a quarter wave from the ground are installed to make use of the ground as a reflector.

FWIW: Lack of Traps do not make a Dipole -and- Traps do not make a Slopper.

TRAPS: Are bassically used to Shorten the Length of the Antenna and/or Add Greater Band Width (Multi-Band Capability) to an Antenna.

IMHO: For "Receive" ONLY Antennas that are intended for a Broad-Band BCL & SWL Antenna Applications: 500kHz to 30 MHz. The Windom Antenna is the Better Choice over the Dipole. Like the Dipole the Windom can be installed Flat, Tilted, and Inverted "V".

I Found it..

http://www.usascan.com/files/bc796d.cfm

FEATURES:

Digital Capable - APCO Project 25 Digital Capable. Now compatible with 9,600 baud APCO digital control channel with digital voice. Not compatible with AGEIS, ASTRO or ESAS systems. With your purchase of a BC796DGV scanner from Communications Electronics, the P-25 APCO Project 25 Digital Card is included, free. When the P-25 card is installed, you can monitor public safety organizations who currently use conventional, trunked at 3,600 and 9,600 baud analog control channel and digital voice and mixed mode APCO Project 25 systems.
TrunkTracker III - Search for and monitor all the groups within a specific trunked system. Lockout unwanted groups during the search and save other groups to scan lists. (EDACS□, Motorola, E.F. Johnson). Follow VHF High Band, UHF 800/900 MHz trunked public safety and public service systems just as if conventional two-way communications were used.
Multi-Track - Track more than one trunking system at a time. Scan conventional and trunked systems at the same time.
1,000 Channels - Program one frequency into each channel. You must have at least one channel programmed to use the scan mode.
27 Bands - Includes 27 bands, with aircraft and 800 MHz frequency coverage.
Continuous Band Coverage (25 MHz TO 1.3 GHz) - Allows coverage from virtually every frequency from 25 MHz to 1.3 GHz excluding the cellular bands and UHF TV band, so you can tune into police, fire, weather, ambulance, aircraft, military, "Ham" radio and much more.
10 Banks - 10 banks with 100 channels each are useful for storing similar frequencies to maintain faster scanning cycles or for storing all the frequencies of a trunked system.
10 Priority Channels - You can assign one priority channel in each bank. Assigning a priority channel allows you to keep track of activity on your most important channel(s) while monitoring other channels for transmissions. You can also assign trunking priority talk groups. When Priority Scan is turned On, your scanner checks the priority channel in the banks you selected every 2 seconds for activity. If a signal is present on the priority channel, your scanner monitors the channel until the transmission ends, then resumes normal scanning. You can designate one channel in each bank as a Priority Channel. By default, the first channel in each bank is the Priority Channel, but you can change this setting.
Priority Plus Scan - Allows you to scan only priority channels.

Preprogrammed Service Searches (10) - This feature allows you to toggle through preprogrammed public safety, news media TV broadcast audio, Amateur (ham) radio, CB radio, Family Radio Service, special low power, railroad, aircraft, marine, racing and weather frequencies.
Unique Data Skip - Allows your scanner to skip unwanted data transmissions and reduces birdies.
Memory Backup - If power is disconnected, the frequencies programmed in your scanner are retained in memory.
Direct Channel Access - Jump directly to any channel without stepping through other channels or entering menu mode.
RF Attenuator - The BC796D comes with an RF Attenuation feature. If you are near an unusually strong signal source, the signal may overload the scanner. The RF Attenuation features works in all modes and attenuates (reduces) the incoming signal strength to prevent stronger signals from overloading the scanner.
PC Programmable - This feature allows the user to remotely program and control the scanner using third party software (available from www.usascan.com). Optional baud rates include 2400, 4800, 9600 (default) and 19200 operating through the scanner's DB-9 RS-232C port.
Turbo Search - Increases the search speed to 300 steps per second when searching transmission bands with 5 KHz steps.
Turbo Scan - This lightning fast technology allows you to scan and search nearly 100 channels or steps per second.
Auto Store - The BC796D can automatically store any found active frequencies into an assigned bank.
CTCSS/DCS - This feature allows the user to assign analog and digital subaudible tone codes to a specific frequency in memory. The scanner will also search for unknown CTCSS and DCS tones.
National Weather Radio - Can be programmed to receive special localized weather warnings broadcast by NOAA. The scanner is compatible with warning siren and message transmissions.
Specific Area Message Encoding (S.A.M.E.) weather alert - S.A.M.E. is NOAA's coded emergency weather signals that identify a specific geographic area affected by an emergency. In weather alert with S.A.M.E. mode, your scanner functions as a county specific severe weather warning radio. To obtain further information about S.A.M.E. and FIPS code, visit http://www.nws.noaa.gov/nwr/index.html.
FIPS Code - This feature allows you to input a six-digit code Federal Information Processing System (FIPS) code that will designate a localized severe weather warning. The BC796D can decode the 6-digit FIPS code established by the National Weather Service (NWS). This FIPS code identifies geographic areas anywhere in the United States, US territories and US possessions. Programming the FIPS code is necessary to receive S.A.M.E. alerts about weather occurring in a particular area. To obtain a FIPS code for your area, call the National Weather Service toll free at 1-888-697-7263 or visit http://205.156.54.206/nwr/nwrsame.htm.
Dimmer - Allows you to change the brightness of the display.

Enter Lock - Allows you to lockout the keypad to prevent reprogramming of channels, talkgroups and tones.
Key Beep Option - Allows you to turn the key beep on or off.
Screen Mask - Screen Mask allows you to limit what appears on the display to the alpha tags that you have set for a channel along with a few function icons. Screen Mask removes the frequency, receiving mode tone data and signal strength bars. This mode is particularly useful in public safety vehicles where "information overload" is already a problem. Screen Mask does not work in Search mode.
Reverse Mode - This key will allow you to observe the reverse frequency of the repeater. While pressing "RVRS", the standard repeater pair frequency will be displayed.
Channel Step Selection - You can set channel steps, 5 kHz to 100 kHz or Auto, in conventional mode or chain search mode. The default receive mode should be the proper mode setting in almost all cases. You may wish to set some VHF channels for NFM mode, depending on any adjacent channel interference problems. WFM is typically used for broadcast frequencies such as TV audio or FM radio.
Mute On/Off - Allows you to manually turn the mute function on or off.
Receiving Mode Selection - You can set the receiving mode, AM or FM in conventional mode or chain search mode.
Duplicate Frequency Alert - If you enter a frequency which has been stored in another channel, you will hear a beep and the channel stored displays a duplicate warning message.
2 Line Alpha Display - You can customize your scanner by storing text tags for easy identification of banks, channel transmission, trunking talk group ID and more. Allows for alpha tagging display of channel, bank or search range.
Control Channel Only Mode - Allows the user to automatically trunk certain systems by simply programming the control channel.
Backlit Full-Frequency Display - Shows the channels being scanned and the frequency entered into each channel with an easy-to-read backlit display for enhanced night visibility.
Clone Feature - Allows for cloning of another scanner's programmed frequencies. (The two scanner's must be connected by a cloning cable for the cloning process to take place.)
Alpha Tagging - Allows the user to assign an alpha description to each channel, trunking talk group and bank.
Beep Alert - You can set a Beep Alert on a per-channel basis to alert you when specific frequencies are active. For example, you may wish to be alerted anytime a mutual aid fire frequency is active. With beep alert, you will hear three
beeps at the start of each transmission that you have flagged as such. You will also notice that as you scroll pass the flagged channel (s), you will hear three beeps.
Record Function - Allows the user to designate a channel to be recorded by an external device. The user will be able to select between ON and OFF. The default setting is OFF. An icon will appear in the LCD when a channel has been assigned the record feature

(requires an external recording device.)
VFO Control - Allows the user to tune through frequencies, channels, alpha characters and more with the handy VFO tuning knob.
Menu-Driven Design - This function allows advanced programming and control operation through the easy-to-use menu system.
Frequency Delay Selection - A default delay of 2 seconds is automatically set for each frequency or talk group A different delay can be set for each programmed channel so that when scan or search stops on a channel there is a brief pause before the scanning cycle resumes. To set the delay feature, enter into the menu mode.
Negative Delay Selection - Setting negative delay periods are useful if you are only interested in small segments of conversations. For example: If you set a -5 second delay, you will only hear 5 seconds of the conversation and then the scanner will resume scanning, whether or not the conversation is finished.
Total Channel Control - Allows the user to program delay, step, mode (adjustable) priority, attenuation and more on a per-channel basis.
Chain search mode - When the scanner finds an active frequency, the trunk tracking system will be active. Four frequency plans apply to the Control Channel Only feature
Trunk Search - Search for and monitor all the groups within a trunked system. Lockout unwanted groups during the search and save other groups to scan lists.
Trunk Lockout - Lockout groups you don't wish to monitor, (including data groups) from the trunked system.
Trunk Delay - Apply a five second delay to trunking groups so that both sides of a conversation can be heard, even if the trunking frequencies change between replies.
One Touch Weather - Automatically scans all national weather channels with a single touch.

Turbo Scan - This lightning fast technology allows you to scan and search nearly 100 channels or steps per second.
Memory Backup - Retains frequencies entered for more than 3 days without batteries or during a power failure.
Programmable Search - Allows you to find new frequencies in any of the bands.
Manual Channel Access - Go directly to any channels without stepping through other channels.
SPECIFICATIONS:

CHANNELS
1,000 Channels (100 channels x 10 Banks)

BANDS 27 Bands
PREPROGRAMMED SERVICES
Service Search menus are preprogrammed services used across the United States. Select services from the following: Weather, Public Safety, news, TV broadcast, Amateur (ham) radio, Marine, Railroad, Aircraft, CB radio, Family Radio Service.

FREQUENCY RANGE
25.0000 - 26.9600 MHz (Petroleum Products & Broadcast Pickup)
26.9650 - 27.4050 MHz (CB Radio)
27.4100 - 27.9950 MHz (Business & Forest Products)
28.0000 - 29.6900 MHz (10 Meter Amateur Band)
29.7000 - 49.9900 MHz (VHF Low Band)
50.0000 - 53.9900 MHz (6 Meter Amateur Band)
54.0000 - 71.9500 MHz (VHF TV)
72.0000 - 75.9950 MHz (Intersystem & Astronomy)
76.0000 - 87.9500 MHz (VHF TV)
88.0000 - 107.9000 MHz (FM Broadcast)
108.0000 - 136.9750 MHz (Aircraft Band)
137.0000 - 143.9950 MHz (Military Land Mobile)
144.0000 - 147.9950 MHz (2 Meter Amateur Band)
148.0000 - 161.9950 (VHF High Band - 5 KHz spacing)
162.000-173.9875 MHz (VHF High Band - 12.5 KHz spacing)
174.0000 - 215.9500 MHz (VHF TV)
216.0000 - 224.9950 MHz (1.25 Meter Amateur)
225.0000 - 399.9500 MHz (UHF Aircraft Band)
400.0000 - 405.9875 MHz (UHF Aircraft Band)
406.0000 - 419.9875 MHz (Federal Government Land Mobile)
420.0000 - 449.9875 MHz (70 cm Amateur Band)
450.0000 - 469.9875 MHz (UHF Standard Band)
470.0000 - 512.0000 MHz (Public Service & TV Band)
806.0000 - 823.9875 MHz (Public Service Band)
849.0125 - 868.9875 MHz (Public Service Band)
894.0125 - 956.0000 MHz (Public Service Band)
1240.0000 - 1300.0000 MHz (25 cm Amateur Band)

WEATHER FREQUENCY
162.4000 - 165.5500 MHz (25 kHz Step)

DISPLAY
Full LCD (with back light)
(BANK, LIST, SCAN, SEARCH, HOLD, P RI, DLY, L/O, LINE, FREQ, CHAN,
ALPHA, RMT, AUTO, ATT, ALT)

CONTROLS/SWITCHES
Volume/Squelch Control with power ON/OFF switch
VFO Rotary Encoder with Pulse Switch

POWER REQUIREMENTS
DC 13.8V (External Power Jack)

EXTERNAL JACKS
Antenna Jack: BNC Type
Phone Jack: 3.5 Ø
Record Jack: 3.5 Ø
DC Power Jack: 5.5 Ø
Remote Interface Jack: D-Sub 9-pin

INTERNAL SPEAKER
8 ohm, 2 watts (56 Ø)

SCAN RATE
Up to 100 channels per second

MODES
AM/FM/WFM (adjustable per channel)

STEP SIZES (kHz)
5, 7.5, 10, 12.5, 25, 50, 100

SCAN DELAY
none, 1, 2, 4, infinite (stay on until Resume is pressed), -2, -5, -10 seconds

AUDIO OUTPUT
8 Resistance Load

ANTENNA
50 ohms

OPERATING TEMPERATURE
-4° F - 140° F
-20° C - 60° C

STORAGE TEMPERATURE
-22° F - 140° F
-30° C - 60° C

SIZE
7-5/8" Wide x 6-15/16" Deep x 2-13/16" High
195.0 mm Wide x 177.0 mm Deep x 72.0 mm High

WEIGHT
2.93 pounds
1.33 kg

UPC CODE
0-45799-66666-0

MASTER CARTON QUANTITY
6

SINGLE UNIT CARTON DIMENSIONS
12-3/4" Wide x 8-1/2" Deep x 4" High

INCLUDED ACCESSORIES
P-25 digital card, Telescopic Antenna, AC Adapter (AD580U), Cigarette Lighter Cord, DC Cord, Mounting Bracket with Screws, Owner's Manual, Trunking Frequency Guide Book, E-Scanner programming Software CD-ROM, Screwdriver

good question.

I have no idea, It wasn't in the link because www.usascan.com doesn't know yet. (at least I'm assuming that).

If I were going to buy another scanner, I think I would get a BC780XLT. It has plenty of stuff, and the price has to be cheaper than the newer models that are out.

I was just wondering if anybody saw anthing in the specs of this new one, that would make it worth the extra money. (again, I'm assuming it will be about $100 more than the current model.)

thanks.

it is exactly the same as the bearcat 780 and the price was said and dont quote me now :) around 600.00 .the only thing diffrent as i said is more channles,and the ability to pick up the apco 25.which illinois and mo do not use .but it is the same exact scanner.i have the bearcat 780 xlt and its great with adiscone and or the wip i pick up everything including the tropo on the vhf low band .and wants you learn it its easy i only had it a month and talked my brother into it on the phone in nj on putting in his police freq on 900 mhz and setting it up and i surprised myself that we got it right the first time:) but you cant go wrong 73 ron trotto,waggoner,illinois

Is this because of this new internet worm that looks like it came from Microsoft? I have gotten over 100 emails in the past 24 hours from people who are infected by this. all using my junkmail email account.

has anyone else had this same problem?

thanks.

64. SkyWire Balun

Yahoo group: SkyWires
Date: 2003-09-21 19:58:13 UTC
From: exemptfromlife
Topic: 64 Message: 64

Does anybody have any opinions about using a balun for a SkyWire Loop Antenna?

If you use one, is it only to aid in transmission?

Is it for 50 ohm coax?

Is it a 4:1 or 1:1 or something else?

Thanks.

65. Re: SkyWire Balun

Yahoo group: SkyWires

From: R H F
Topic: 64 Message: 65

EfL,

1. I would say that depends on what your use of the SkyWire Loop Antenna was going to be:

? For use as a "SWL" Receiving Loop Antenna ONLY ?
- - - Try a 9:1 or 16:1 Balun

? For use as a Transmitting and Receiving Antenna ?
- - - Try a 1:1 or 4:1 Balun

2. Is this a true Full Wave SkyWire Loop Antenna:

? Cut to 530 Feet at 40 Ft for the 160 Metre Band ?
- - - Single band use 1:1 & Multi-Band use 4:1

? Mid-Size Loop of 272 Feet Long at 30-40 Ft for 80 Metre Band ?
- - - Single band use 1:1 & Multi-Band use 4:1

? Smaller 40 Metre Band 140 Foot size at 30 Ft ?
- - - Single band use 1:1 & Multi-Band use 4:1

3. Are you going to use a Ladder Line Matching Section between the Loop and Coax Cable or connect directly between the Loop and the Coax Cable?

? Loop > Ladder Line > Coax Cable ? (Transmitting at 40 Ft)
- - - Single band use 1:1 & Multi-Band use 4:1

? Loop > Coax Cable ? (Receiving "SWL" ONLY at 20 Ft)
- - - Multi-Band use 9:1 or 16:1

IMHO: Using a 9:1 or 16:1 Balun (Matching Transformer) with a SkyWire Loop Antenna makes the Loop more 'broad banded' and improves its reception on all bands above and below the design frequency it was Cut-To-Length for (Or Not!).

* Radio Amateurs will indeed cut their SkyWire Loop Antennas to a specific length and mount them at the required height to get the maximum power radiated from their antenna into the air.
- - - They will use a 1:1 or 4:1 Balun

* Shortwave Listeners "SWLs" will (most of the time) make their 'so called' SkyWire Loop Antennas to fit the available space at a reasonable height (a de-facto Random Wire Loop Antenna).
- - - They should use a 9:1 or 16:1 Balun

BALUNS: To Transmit, or To Receive... That Is The Question !

I had planned on using coax instead of ladder line, but I have heard some great things about using a ladder line.

I've never seen a 9:1 or 16: 1 balun, but then again, I didn't know they existed.

do you know anyplace that sells a resonably priced one? or a certain brand, that would be better than others?

I was going to string up about 400 feet of skywire. I figured for reception, the length didn't have to be exact. The height will be about 35 feet on average.

I currently have a a dipole, and I will be taking it down and replacing it with the skywire.

I just finished grounding the dipole for lightining using an 8 foot copper clad grounding rod, and 1/0 gauge copper wire to a metal panel, and then using a pollyphaser lightining arrestor bolted to the panel, and the 1/0 wire bolted to the panel.

This actually seemed to improve my reception a small bit.

I wanted the lightining protection in place before I ran the skywire.

So, that is the current plan, if you can add anything to it, I would really appreciate it.

thanks.

EfL,

Do-It-Yourself: The simple Nine-to-One (9:1) Balun
http://www.hard-core-dx.com/nordicdx/antenna/feed/9_1balun.html

The "Balun" Defined
http://searchnetworking.techtarget.com/sDefinition/0,,sid7_gci342213,
00.html

NOTE: With (Matching) Transformers it is the "Ratio" of the Squares
of the Number of Turns that 'defines' the "Ratio" of the Matching
Transformer. Here are some straight math common examples:

* One to One "1:1" = (1X1) : (1X1) = 1 Turn to 1 Turn

* Four to One "4:1" = (2X2) : (1X1) = 2 Turns to 1 Turn

* Nine to One "9:1" = (3X3) : (1X1) = 3 Turns to 1 Turn

* Sixteen to One "16:1" = (4X4) : (1X1) = 4 Turns to 1 Turn

* Twenty-Five to One "25:1" = (5X5) : (1X1) = 5 Turns to 1 Turn

* Thirty-Six "36:1" = (6X6) : (1X1) = 6 Turns to 1 Turn

Here is a good read from Hard-Core-DX {DOT} Com
http://www2.hard-core-dx.com/nordicdx/antenna/feed/
Amateurs are almost religious about balancing their antennas - in
order to get the most power into, and out off, the antenna. But
receiving antennas, do they really have to be balanced? Well, yes
and no. It all depends... Read, and learn, more about this
subject:
* The purpose of a balun
* "Matching less important for reception"
* "Matching is important - it gives better reception"
* "Not necessary to balance longwires"
* "You must use a balun to balance your dipole..."
* Balun or Antenna Tuner? It all depends...

Balanced Self Matching Feed Line System

Topic: 64 Message: 69

EfL,

Here is a simple "KIT" to make a Toroidal Core Balun and Antenna to
FeedLine Matching Transformer that is offered on eBay.

http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=3048336377

The Balun Kit is for 1:1 and 4:1 Balun, but can easily wound for:

Nine-to-One (9:1) Balun.
Primary (Antenna) Turns to Secondary (FeedLine) Turns.
21 Turns to 7 Turns
30 Turns to 10 Turns
42 Turns to 14 Turns

Sixteen-to-One (16:1) Balun.
Primary (Antenna) Turns to Secondary (FeedLine) Turns.
28 Turns to 7 Turns
36 Turns to 9 Turns
44 Turns to 11 Turns

First: Use large enough wire for the Primary (Antenna) Windings to
cover 85%-99% of the Toroid's Area. Or, "Space Evenly" the Primary
(Antenna) Windings 'far enough apart' to cover 85%-99% of the
Toroid's Area.

Second: Wind the Secondary (FeedLine) Windings over the Primary
(Antenna) Windings. Use the same size wire "Spaced Evenly" to wrap
the Secondary (FeedLine) Windings to cover 85%-99% of the Toroid's
Area.

iane ~ RHF
.
.

72. Scantenna and TV satellite dish on same antenna tower.

Yahoo group: SkyWires
Date: 2003-09-24 03:12:42 UTC
From: exemptfromlife
Topic: 72 Message: 72

Does anybody have any experience with putting a scanner antenna and their TV satellite dish on the same antenna?

I want to know if there will be any interference issues.

Thanks.

This is on their corportate website if anybody is interested..

http://www.rohnnet.com

thanks.

74. My New SkyWire Loop Antenna

Yahoo group: SkyWires
Date: 2003-10-03 13:22:14 UTC
From: exemptfromlife
Topic: 74 Message: 74

I just finished taking down my old dipole yesterday, and putting up my new 500 foot SkyWire in my back yard.

At first I thought that 500 foot of wire was a lot, but actually when I finished it was just the right size to cover the back yard. I have it up at about 30 feet, I realize that most articles claim it should be at a minimum of 40' but the trees I strung it from aren't that tall.

It consists of 12 gauge stranded wire that is insulated, and fed with coax.

I plan on spending the weekend testing the reception on it to see how it does. So far I'm noticing signals that I know I have not been able to get before, and others that were weak, and now are worth listening to.

I'll let everybody know how it does.

Thanks.

Just out of curiosity, how are you feeding the wire? Definitely let
us know how it works.

76. Insulated or bare wire?

Yahoo group: SkyWires

From: professormobesser
Topic: 76 Message: 76

Are most folks using insulated wire or bare wire for their skywire loops?
Are there any differences in performance?
Is there any arcing to tree branches from bare wire when using 100 watts or less?

77. Re: Insulated or bare wire?

From: exemptfromlife
Topic: 76 Message: 77

I have read that people use both. I've heard arguments on both sides.
I chose insulated for a few reasons.

(1) My SkyWire is held up by trees and the wire has to run through some of the branches. I didn't want it to short out on the
branches.

(2) It was somewhat hard for me to find a heavy gauge like #12 that wasn't insulated.

(3) The insulation helps in the strength of wire, and makes it slide through the insulators easier. Since I wanted a heavy gauge to survive in high winds because of the tree support factor, I considered the insulation as a plus.

(4) If radio waves can go through tree branches, leaves, wooden houses, etc, then one millimeter of plastic insulation shouldn't be
much of a degradation in signal strength.

(5) I'm just guessing at this last point, but I have heard that during snow storms the charged particles hitting a wire will build up a static charge. I assume the people who wrote this were talking about a bare wire, because I can't see how snow hitting an insulated
wire would cause the same degree of static build-up.

If I had an open field to run my SkyWire and were going to plant eight or so tower masts in an octagon shape to support a wire, I would probably go the extra distance and mail order some 12 gauge bare stranded wire. I'm sure that given enough space (ie. Open field), you could run the wires with tree supports and rig it in a manner than the bare wire would never touch the trees and short out.

My lot is only 90 feet wide, and with trees planted on both sides this leaves only about 30 feet of open space in some areas.

Thanks.

i am running a full size 160 meter loop skywire with 530 feet of wire at 60 feet above ground. I feed my loop with 200 feet of 450 ladder line. In the shack I use an old AIR-DUX 4 to 1 BALUN which is the old air wound coil type. The BALUN is then connected to the internal autotuner in my ICOM IC-756 PRO II. The autotuner has no problem with the loop antenna system and tunes fine on all HF bands. I have scrounged up 1,590 feet of insulated wire which I plan on installing when all the leaves are off the trees this late fall. This will be a 3 times 160 meter loop. It should be fun this winter testing the new larger loop skywire!

That sounds pretty cool.

I feed mine with coax, but at some point will change to either a
better grade of coax, or maybe a ladder line.

If I only want to receive is there an advantage to using a ladder
line, balun, and tuner?

thanks.

Ladder line is very low loss, light in weight, and
costs less than coax. It will also not burn up under
high power at high SWR conditions along the ladder
line. If your only going to receive you do not need
the BALUN or tuner at all.

I live on five acres of sloping property with lots of pine trees.

I look out my kitchen window and I'm looking over the top of my tall garage roof less than 80 feet away.

Should I forget about a SkyWire for receiving since I'd prefer omnidirectional capability?

Iden - Northern CA

Topic: 82 Message: 83

If the skywire is built correctly it should be omni directional. Much more than a dipole.

You should try and get it to form a circle. Impossible given you can only hang so many lines to so many trees. I pentagon shape would be better than a square, a square would be better than a rectangle, etc.

Mine is a Rectangle, because that I have to live with the cards I'm delt in terms of the trees that already exist on my property.

A lot of skywires encircle existing buildings/houses ,etc.

I don't know about the sloping landscape issue. I've been told to keep it as parallel to the ground as possible.

so for recieving I should use a ladder line instead of coax?

at what point do I change over to coax? do I bring the ladder line
all the way into the house to the reciever?

what about electrical interference since the ladder line isn't
shielded?

thanks.

Use what you like, ladder line or coax. If your
already using coax stick with it. If you want to
switch to ladder line, just do it!
> at what point do I change over to coax? do I bring
> the ladder line
> all the way into the house to the reciever?
If you can bring the ladder line all the way in to the
back of the radio that would be best. Ladder line must
be used with standoff insulators so nothing is closer
than it's own width from stuff like wood and metal
which would cause problems. If it's a problem to do
that just switch over to coax anywhere you want.
> what about electrical interference since the ladder
> line isn't
> shielded?
Ladder line is shielded but not in the way coax is.
The parallel wires cancel out the interference. This
is the reason you need standoff insulators when your
close to wood or metal objects as they would upset the
balance in the parallel wires.

> I might upgrade to a better grade of coax
> I have the cheapest stuff radio shack sells now, I thinks
> R59 or something.

Look at the coax attenuation table:
http://www.therfc.com/attenrat.htm

If your RG-59 lead-in is 100 feet long, then at 10 MHz
you will have a 1.1 dB loss. That's not much.

If you replace it with RG-8 coax, the loss will drop to
.55 dB.

That's a difference of .55 dB for a 100 feet at 10 MHz.
I doubt that you could hear the difference or see
it on an S-meter. It is my understanding that one unit
on a calibrated S-meter represents 6 dB.

Even at 50 MHz, the difference would only be 1.1 dB,
not much.

EfL,

IIRC: Insulated or Bare Wire it does not matter.
- - - Try running a hard rubber/plastic comb through your hair
several times and you will have a static charge build up.

EfL,

Two Reasons to 'use' a Balun (Matching Transformer) with a Receive Only Antenna.

1. Using a Balun (Matching Transformer) between the SkyWire's Loop Antenna and a Coax Feedline can reduce Static Build-Up and help to prevent ESD down the feed line to the radio.

2. Plus for a "Receive Only" Antenna the use of the Balun helps to improve the antenna's broadband potential for better multi-band coverage and a lower noise factor.

Check-Out the Graphs in this ANARC Posting by John Doty.
http://www.anarc.org/naswa/badx/antennas/SWL_longwire.html
"Actually, a fixed matching transformer can dramatically reduce the wild swings in antenna efficiency that a coax fed wire antenna exhibits. " John Doty

Topic: 82 Message: 91

Iden,

The "SkyWire" Horizintal Loop Antenna is 'by design' an All "Omni"
Directional Antenna.

The basic and simple SkyWire Loop Antenna is built relatively large
(one wavelength); but close (low) to the ground (less than a quarter
wavelength): with regard to the lowest operating frequency.
* 160 Metre Band = 529 Feet (1 WL) at 40 Feet (0.08 WL) High
* 80 Metre Band = 268 Feet (1 WL) at 40 Feet (0.15 WL) High
* 40 Metre Band = 141 Feet (1 WL) at 30 Feet (0.21 WL) High
* 20 Metre Band = 71 Feet (1 WL) at 20 Feet (0.28 WL) High

ABOUT HEIGHT: For a "Receive Only" SkyWire Loop Antenna keeping
the 'average' height above ground in the range of 30-40 is a
reasonable goal in its design and construction for the Lower 160 and
80 Metre Bands. For the "Middle" SW Bands 25-35 Feet and for "Upper"
SW Bands 20-30 Feet.

Frequency vs. Wavelength (Ham and SW Meter Bands)
http://www.dxing.com/frequenc.htm

To some degree a SkyWire Loop Antenna is a form of NVIS "Near
Vertical Incident Skywave" Antenna.
http://www.qsl.net/k5eph/nvis.htm

FWIW: If a "Receive Only" SkyWire Loop Antenna is 'not' going to be
used for AM/MW/BCB and Tropic Bands. Then it can be made smaller
and 'designed' to be 'used' on one of the lower Shortwave Broadcast
Bands "60" or "49" Meters.

* SW "60" Meter Band (4.75-5.0 MHz) and cut to 206 Feet (52 Feet per
side) and mounted as low as 20 feet high.

* SW "49" Meter Band (5.95-6.25 MHz) and cut to 165 Feet (41 Feet per
side) and mounted as low as 15 feet high.

NOTE: For a "Receive Only" SkyWire Loop Antenna the only caution is
not to by accident construct a "Rhombic Antenna"
http://www.mindspring.com/~cummings7/rhombic.html
- - - Basically a 'Diamond' Shaped Antenna (twice as long as it is
wide) and fed at one of the narrow corners.

EfL,

AY Technologies Products
MODEL TRX-9
9:1 Receive Antenna Transformer
http://www.aytechnologies.com/Products/products.htm

Since you are using this SkyWire Horizontal Loop Antenna for "Receive Only" and plan on using a Balun. IMHO - The 'better' method is to use the Balun at the Antenna Loop Element (Head) with a co-located ground point/wire/rod. Simply use Coax Cable directly from the Antenna to the radio/receiver. This should result in a 'lower noise factor' for the Antenna, Ground and FeedLine System.

However, If you were a HAM trying to 'match' an Antenna to a transmitter for a specific frequency band. Then using a section of Ladder Line to 'match' the Antenna to the Coax Cable Feedline would be one method of acomplishing this with or without a Balun.

Iden,

? "On sloping property, my guess is that could change." ?

If the Antenna is elevated specifically 1/4 or a 1/2 Wavelength above the Ground Plane Surface: The antenna's directivity may be affected by the lay of the ground as the ground itself acts as a tuned (phased) reflector. At 'Resonance' the Antenna would appear to be "Tilted".

However, since in general the SkyWire Horizontal Loop Antenna is usually placed around 1/12 to 1/6 Wavelength over the ground: The antenna acts more like a NVIS type antenna and should exhibit Omni-Directional Characteristics.

RHF,

Currently the setup is like this.

500 foot of #12 stranded wire in sort of a rectangle loop.

connected one side to R59 coax center connector, and the other side to the copper braid.

50 foot of R59 coax down to a metal box housed pollyphaser lightning arrestor. about 6 foot of 4/0 (200 amp service panel size)gauge copper wire attached to the metal box and the other end to an 8 foot copper clad grounding rod, hammered about 7/8 of the way into the ground directly under the metal box.

Then another run of 50 foot R59 coax from the pollyphaser to the reciever.

a #14 ground wire from the GND screw on the back of the reciever to another grounding rod (4ft) copper pipe hammered into the ground. near the lighting grounding rod.

I had thought that perhaps mounting this 9:1 balun on the outside of the metal box (no room inside) and then 50 foot of ladder line down from the skywire (replacing the first coax run) to the balun, then a short patch cable piece of coax to the pollyphaser.

I don't know if it would be worth the expense or not considering this ia receiving antenna and not a transmitting one.

thanks.

I noticed that when I put the pollyphaser/metal box into the system, the noise dropped off quite a bit.

101. My Skywire current setup (diagram)

EfL,

TIP: Change one 'item' in an Antenna System at a time and record
the "Reception" Performance Characteristics "Before-&-After".
- - - Make incremental improvements and learn from each one as you go
to build your personal knowledge base.

Big Plus: Get a Note Book [My Antenna Note Book #1] and "Document"
what you do and the 'results' that you get.
+ Read/Talk/Question
+ + Then Try Out Your Ideas (Just Do It!)
+ + + Learn for Yourself !

I currently have WindomHSQ from antennas and more. In my ARRL Antenna book, it kind of has the features of both. Anyways, I want to try a homebrew loop. Right now, my Arrl Antenna book is loaned out. It does mention the skywire loop and that's where I learned about it. Anyways, it had the general impedances at the resonate frequencies, how to feed it, etc. Anyways, I no longer have the calculations or anything to go by, so here's what I want to do. I'm hoping someone can fill in the blanks for me?
I want to build a 75 meter loop with a balun and coax. Right now I only have the radio's tuner. So here's what I had in mind. Antenna to balun using ladder line, then balun to coax to come through the house.

ProfessorMobesser,

I think what I am suggesting is that using Insulated Wire will 'not' necessarily protect an Antenna from having a "Static Charge" build-up on the Antenna Element.

Given the 'right' weather conditions a long piece of Nylon Fishing Line place up in the air like an antenna; will build-up a "Static Charge". Hey, this could be connected to the lead of a NE-2 with the other lead grounded as a "Static Discharge Conditions Build-Up Warning Indicator" :o)

272 feet of wire and any length of coax or ladder line
or both may be used. My 160 meter loop has 530 feet of
wire and 200 feet of 450 ohm ladder line running to an
old AIR-DUX 4 to 1 BALUN mounted just under a window
where two ceramic insulators are mounted to a wood
board in the window casing allowing the ladder line to
feed into the house and to the BALUN. You could place
a modern BALUN on the outside of the house and run
coax through the house with no problem. I use the
AIR-DUX BALUN and a short run of coax about 4 feet
long to connect directly to my ICOM IC-756 PRO II and
use the internal antenna tuner which tunes the antenna
anywhere on all the HF bands with no problem. When I
run my Heathkit SB-1000 amplifier and SA-2060A tuner
the AIR-DUX BALUN is bypassed by a shout run of 450
ohm ladder line from the SA-2060A tuner to the point
where the AIR-DUX BALUN would normally connect to the
ceramic insulators. I only operate the Amplifier on
160 meters when the noise levels are high on that
band. Late this Fall when all the leaves have fallen
from the trees I will be putting up a 3 times 160
meter loop. That is 1,590 feet of wire in a large loop
running through the forest behind the house up about
30 feet using nail on electric fence insulators on the
trees.

From: cpa2000
Topic: 107 Message: 107

I am going to put up a horizontal loop @ about 60' in hopes of having
a
decent 160-10 antenna. Is there any adavntage to increasing the the
total
length from 1 wavelength at the lowest freq. (about 530') to 2
wavelengths(1,060'). I have the space & the wire & I'm wondering if
it's
worth the extra effort.

Also, am I better off with a 3/8 WL inverted L on 160.

Size does matter. ;-)

Yes from everything I have read, you want it as large and as high as you can get away with.

The three keys to a good skywire are these.

(1) Get it as high as reasonable possible.

(2) Make it as close to a true circle as possible.

(3) Keep it as parallel to the earth as possible.

Follow these three rules and you are well on your way to having a really cool antenna.

keep us posted on your progress.

CPA2000,

For a Full WaveLength SkyWire Horizontal Loop Antenna at 160 Meters.
The 530 Feet One WaveLength would be about right for 160 Meters.
- - - And work well thru 10 Meters.

* A Height of about 66 Feet would be 1/8 WL for 160 Meters.

* * Ideally a Height of about 132 Feet would be 1/4 WL for 160 Meters
and naturally would be better.

I will repeat myself that most SkyWire Horizontal Loop Antennas that
are mounted at a 'height' of 30-40 Feet are acting more like NVIS
Type Antennas = IMHO.

I understand that the Horz. Loop is essentially a cloud warmer. My question is this, does increasing the length to 1060 feet (i.e. 2 wl on 160) will I get better performance on 160 than if it was 1 wl.

Has anyone had a 1 wl 160 loop & increased it to 2 wl & noticed an improvement on that band.

I'm trying to determine whether it's worth the extra wire & effort.

Terry [W8EJO],

First let me say, I am not a Radio Amateur "HAM" and do NOT use
Antennas to 'transmit'.

But, for specific use on the 160 Metre Band for both Transmission
and Reception. I would say the 530 Foot "One WaveLength" Size
SkyWire Antenna would be better with a 'direct' Coax-to-Antenna Wire
Element connection. Or, you could use 450 Ladder-Line for the
FeedLine.

However, for a "Receive Only" Antenna the 1060 Foot SkyWire Antenna
using a Balun between the Coax and the Antenna's Wire Element would
give better broad band results from the AM/MW Broadcast Band to the
10 Metre Band and beyond.

Warning: I am a bit fanatical here...

There are many hams in Alaska who run skywires.
Most are 270" (mine is) some are 540" a few are 1180".
Our conditions up are sometimes so poor that the guys
have tried all kinds of antennas. The loop comes out
on top most of the time. Some big gun DXers run full
sized verticals or half squares or 4 element vertical
phased arrays for DX but for net work, most of the strong
signal regulars are running an 80 meter or larger loop.

One fellow with an 1180" loop has the loudest signal on our
80 meter nets. He also opens the band on 20 to the states and
europe.

He is the most active person up here on 160 meters.

I believe he had a 540 loop and was happy when he increased
the size to 1180.

If you do make your loop 1180 and you use the loop on 160
you will see a clover leaf pattern with some fair nulls
be careful to point your nulls to strategic locations.

The loop is only a cloud warmer on its lowest frequency.
eg. a 270 80 meter skywire is an NVIS antenna (points
straight up) This is a good thing... Usually on the
lowest frequencies you want to work out to about 800 miles.
and a Near Vertical Incidence Skywave?? antennea is the ticket
for that situation.

We have done tests here and the 80 meter loop on 80 works
really up to 20 db better than a dipole to about 600 miles on 80.

This does not mean that the antenna does not work on long haul
on 80. I have talked to the east coast as the grey line passes
over them from here on my 80 meter loop.

What most people dont get is that these loops are not "cloud
warmers" on the higher bands. They act like omnidirectional
beams on the higher frequencies. Think of them like unterminated
rhombics.

The same fellow above with the 1180 loop also has a tribander
up 60 feet. He said that "In no direction on no band does his
tribander beat his loop in performance". IE. an omnidirectional
beam.

I have used my 270 loop in contests running qrp and often
get "gud sig" when talking to big guns in the contests.

The antenna hears very well. It beats my 88 foot 20 meter extended
double zepp and my full size half wave vertical for 20 on all bands
in all directions except for long haul TX on the new 60 meter band.
With the rules on the 60 meter band I can run about 95 watts into
the vert and still have 50 watts erp but have to drop to 24 watts
on the loop to maintain 50 watts erp. The vertical is way to noisy
to copy any sigs on 60 m so I sometimes transmit on 60 m and
then switch to the loop on RX.

I just reread the last paragraph. I wasnt clear enough.
When I said my loop beats my vert and dipoles what I really
should have said is "My loop KILLS any other antenna I have put
up in my lot as defined by A/B and A/B/C tests with coax switches.
Sometimes my loop is 3 to 5 S units better than my other antennas
that is 60 DB. It doesnt sound possible but I see it all the time.
The Signal to noise ratio is much better on the loop.
Listening to CQWW in horrible conditions this weekend, The loop
was 6 S-units above the noise at S7 to a particular canadian station.
The half wave vert could just detect the station and he was right
at the noise floor at about S4. The ExtDoubleZepp was S2 and about
1 Sunit above the noise. Other stations had different results but
every time I have checked my loop has beat all my other antennas
(with the exception of one time my full sized quarter wave vertical
on 40 beat my loop for a 5 minute period to New Zeland - 5 minutes
later the loop was winning again (The vertical was MUCH noiser
during that time). I think the reason the vert beat the loop
to NZ that time is that I believe I have a null directed to NZ
and for that 5 minute window the low angle perf of the vert beat
my loop in the direction of the loop null.

So long winded answer...

The answer to your question is "YES" put up the huge loop.
It will KILL. And you will have SERIOUS bragging rights.

Tnx to Mike, KL7R & all others who posted on this question. Mike's passionate post, extolling the virtues of the big loop put me over the top & convinced me to put one up. I also checked out the QRP-L list serve & was impressed by the remarks of Seabury Lyon - AA1MY. Seab has (or had) a 1,400' loop @ 60'+ &, like Mike KL7R, raves about it's performance. One neat trick he employed was to suspend the corners of the loop from pulleys so that he could move the feed line along the loop & change his pattern nulls & lobes. Result was a rotatable (pattern) loop. Maybe two (switchable) feedlines accomplishes the same thing. I don't know, I'd have to model it on eznec.

RHF,
I'm not KL7R, but if the rail is being used as a vertical antenna,
which it is as I read the message, the coke bottle would be at the bottom of
the rail, between the end of the rail and the ground. Same principle as
those honking big insulators you see on the bottom of the antenna masts of
the commercial MW stations.

Yeah, Thats it.

I use the chain link fence top rail for the mast.
It is pretty strong and it is cheap. It comes in 21 foot
sections so I used a section and a half for the mast.

I stuck the neck of a coke bottle into the mast at the base
and buried the bottom of the coke bottle in the ground so that
the mast was insulated from ground.

I used a hose clamp to attach my feedline to the mast
I attached the other side to my feedline to a ground.
(my chain link fence posts bonded togeather with the shield
of some rt8 and hose clamps.)

The mast is attached to a 1 foot square piece of plywood using "U"
bolts and the plywood is screwed into the eve of my house.

The top of the mast has a couple of pullys and 3 guy ropes
to steady the top of the mast in winds. I use one pully to
hoist the loop and the other for "experiments".

I actually feed the mast with twinlead too so I can load it
up on 40-10 just like I load up the loop on 160 thru 6.

The 80 meterloop really doesnt like to take power on 160 meters
So I usually wind up shorting the feedline so the loop acts like
a toploaded vertical on 160 working against my fence ground.

It is really quiet on 160 but it is super narrow if loaded as
a loop rather than as a top loaded vert.

The mast is just a support for the loop but serves a dual purpose
in that I can use it as another vertical antenna for testing.

From: exemptfromlife
Topic: 121 Message: 121

I haven't be able to listen to shortwave lately do to the solar activity. Its just not worth fighting the static on some channels.

However, tonight, I was riding my bike after dark and got to see the North Lights better than I have ever seen them this far south. (St. Louis Missouri area).

I hope this clears up in the next few weeks/ months.

Thanks.

Hey you crazy kids, you - I'm new here, my name is Steve (kb8viv)and I'm here in Northeast Ohio..In my search for a new antenna (my old butternut verticle is lookin pretty ragged) I've stumbled upon the horizontal loop..I have to tell you - I really want to erect one of these bad boys...I have a back yard full of woods, but what I originally thought was going to be easy is turning out to be more of a challenge..lots of trees but also lots of branches in the way, foliage, Poison Ivy, etc..

I haven't given up yet, actually tried out my new slingshot/fishing reel contraption..They want close to $100 for that ezhang deal, I made my own for about $20..hihi..anyway, I think I'll have to wait till the leaves are gone from the trees before I get serious...

My goal is to erect an 80 meter loop so that I can (hopefully) work 10-80 meters cw and ssb, appears that this is the antenna to get the job done...If I get it up, not sure how close to a circle or square its gonna but it'll hopefully be good enough..I plan to just feed it with coax..

Do these antenna's actually show low swr on all the bands or does a tuner need to be used on the bands..I read something that appeared to say it had a good match on most of the bands?? Ok, thanks again for any advice..

Steve,

Once some of the leaves fall I am sure it will be easier and worthwhile. I have mine cut for 80 meters feeding it wil ladderline to the ground then a 4:1 balun and coax on into the shack. If you just feed with coax you will need a tuner on 10-40 meters most likely. You can see more on loops on my website http://www.kq8rp.com

Hi Gordon, thanks for the reply..I'm definitely gonna be giving it a heck of a shot (putting up the loop)..As far as feeding, I've read all kinds of different methods..I know that coax will have a little more loss..but I also read that you shouldnt use baluns with tuners as they will heat up...since I plan on using it on 10-80 I'll definitely be using the tuner. Of course, I'll probably experiment a bit with it before it's all said and done..

Ok Gordon, thanks es 73's..

125. radials/ground with a skyloop

Yahoo group: SkyWires
Date: 2003-11-01 12:05:27 UTC
From: desmoface
Topic: 125 Message: 125

Hey kids...Just contemplating my skyloop installation...Has anyone grounded their skyloop? Here's my thought; at the termination of the wire, near the feedpoint, running a wire from the shielded part of the coax to a grounding rod.. Any thoughts on how this would affect operation?? How bout if I added some full or 1/2 wave radials to help minimize ground losses as my setup is going to be fairly low to the ground, especially near the feedpoint of the antenna??

Thanks in advance for any advice?

A loop does not require a ground. If you want to
ground it for safety you would use ladder line from
the loop to a 4 to 1 BALUN close to your ground rod
and ground the BALUN on the unbalanced side. Radials
will cause problems under the loop, dont add them. I
have seen buried loops run just under the soil used by
troops to keep in contact with the command shack miles
away, dipoles also work buried just under the soil. As
there detuned you just make the loop or dipole as
large as you can but you don't want if found...
Several are buried spaced miles apart so the troops
can check in every now and then without transmitting
from the same area every time, and getting captured. A
low to the ground LOOP will still work fine but not as
good as one placed high up in the tall trees or
between towers.

Hi Scott, thanks for the info...I won't bother with grounding the loop then.
When my antenna's aren't being used they are attached to a grounding point
which is in turn attached to an 8 ft ground rod..

I have to order wire and support lines as I just got done setting everything
up for the loop; trimmed a bunch of trees (I could have used a chain saw today
hihi), ran the leaders for the support lines/wire, everything looks good..I'm
a little short on my length, coming in at around 230 ft...although I'm not
accounting for the droop in the wire, which should add a few more feet. I'll
have to improvise if I come up short when I start running wire..

I'm thinking very seriously about getting this for the wire
http://www.davisrf.com/ham1/flexweve.htm and this for the coax
http://www.davisrf.com/ham1/coax.htm, the bury flex looks like the ticket..What did you
guys use for wire??

Fortunately the coax will have a short run of about 25-30 ft into the house
so loss shouldn't be too much of a problem..

Im probably not going to run a balun as they arent supposed to be used with
hi swr's..and I'll be using the loop for 10-80 cw/ssb...I will probably just
put 8 or so loops of coax at the feedpoint just in case and run the coax into my
mfj tuner..I may spring for a better tuner with the money I saved homebrewing
my antenna..

Ok, sorry this was longwinded..I'm psyched to get this loop on the air...I'm
hoping for better performance over my old beat up butternut vertical,
especially on 40 and 80..tnx again..

Steve/KB8VIV,

? How about if I added some full or 1/2 wave radials to help ?

The full wave length "Counterpoise" placed on the ground directly under the Antenna Element might help; depending on your Antenna Height and non-uniform ground/soil conditions.
- - - A 'passive' Counterpoise that is not physically connected to the actual antenna element or feedline.

However, the Half Wave Length "radial" may affect the omni-directional properties of the SKyWire Antennas and SKEW the Antenna's "Propagation" Pattern "?"

Somethings-to-Think-About:

1. Placing a Ground Rod at the Center Point of the SkyWire Loop Antenna. Connecting a 'set' of Six(6)=[60*] or Eight(8)=[45*] "One-Eigth" (1/8th) Wave Length Radials all connected to the Ground Rod and uniformily "Radiating" outward from the Center Point: This may improve the Omni-Directional characteristics of a 'less than perfect' SkyWire Antenna.

2. Maybe a 1/4, 1/2, 5/8 and/or 3/4 Wave Length Loop Counterpoise (s) that is/are uniformily centered on the ground within the larger SkyWire Antenna up in the air.

Note: These mite be worth modeling - For a Look See!

On my 160 meter loop I used 16 guage
insulated/stranded wire with a plastic coat. The stuff
you can find at a building supply store for running
wire inside conduit. Feed line is 200 feet of 450 ohm
twin lead. I use an old AUR-DUX BALUN between the twin
lead and my ICOM IC-756 PRO II and have no problem
using the internal automatic antenna tuner on all the
HF bands. When QRO with the SB-1000 amplifier I use
the 4 to 1 BALUN in the Heathkit SA-2060A tuner with
no problems even at the 1000 watts max power level.
Even running RTTY mode at 400 watts still causes no
problems with the BALUN in the tuner. The AIR-DUX
BALUN is air would coils so there is nothing to heat
up. It's just very large in size!

Hi iane-rhf, thanks for the reply. I think I'm just going to try her out with no ground or radials. I may experiment after its all up and running and I establish some base performance criteria/something to compare to..I'll be ordering up the wire and support rope on Monday...Hopefully next weekend I'll be able to get her up in the air. Thanks again..

Hi Scott. I was going to try twin lead but my house is aluminum sided and it would have to pass through it into the shack..Hence coax...Do you think it'll tune up ok with coax and just running her into the rig?

How long have you had your loop up?? Have you noticed any stretch using regular electrical wire??

Is twinlead as finicky as they say?? I've heard it can't be run near such as trees and has to be kept away from the ground??

Yes,

I grounded mine for lighting protection, and I did notice a
difference in reception /clarity for the better.

I have a 500 foot loop made from 12 gauge stranded wire that is
insulated, that is about 30 feet off the ground. Fed by coax. The
coax center connector soldered to one end of the skywire, and the
shielding braid to the other

Down at the other end of the coax I have a polyphaser lightning
arrestor attached to a metal service box. The coax connects to the
antenna side of the polyphaser, and then a new section of coax to the
equipment side and on into the house.

I have a 0/4 gauge copper wire (thickness is about the diameter of a
dime) running from the metal box, to an 8 foot grounding rod. If
lightning hits it should follow the 0/4 gauge wire to the ground.

Once the coax connects to the SW radio inside, I have a 14 gauge
stranded wire running from the GND (ground) on the back of my radio
back outside and to a different grounded rod made from some old
copper pipe I pounded a few feet into the ground.

I only use my loop for reception and not for transmitting. Right now
the atmosphere is terrible for reception because of the solar
activity, so now is a good time to spend some time planning and not
get in a hurry to get something up, and cut corners.

Good luck..

Coax will work fine, don't worry-be happy!
My loop has been up/down for several years. The only
stretching was from a tree falling across it! I just
soldered the break and put it back up. Twin lead needs
to be at least it's own width away from any objects
to keep the balance between the parallel wires. other
than that I have never had any problems running it.

Hmmmm ..... One way of looking at all antennae are to divide them into those in which antenna currents work against earth, such as various long wires and verticals and those in which antenna currents are balanced within the antenna and not to earth, such as dipoles and loops. The skyloop is a large loop antenna eg 1 wavelength or greater in relation to the frequency transmitted/received.

The challenges in coupling the feedline from the xmitter/receiver to the balanced antenna is to maintain the balance of the antenna, to match antenna impedance to feedline impedance, and to minimize interaction between the antenna and the feedline. If the feedline is coaxial cable some form of RF transformer or balun is used for purposes of maintaining balance and impedance matching while juidical placement of the coax in relation to the antenna is undertaken to mimimize interaction between the antenna and the coax. (after all you usually don't want the feedline to be part of the antenna unless that is part of the design).

Now, given the specifics of your situational question; is it a loop or is it a vertical ??? First, the loop will certainly not be balanced since one side of the feedpoint will be connected to earth with an element (piece of wire of unspecified length). There certainly will be interaction between the ground element and the coax feedline all of which will depend on resonance of these introduced elements.

My guess is that with enough experimentation, tuning of the introduced element, judicial placement of the coax, and connecting the coax to the xmitter/receiver with an antenna tuner you should be able to radiate RF. However as soon as you shift frequency an appreciable amount you will have to go through the operation once again. It is anyone's guess what the radiation characteristics will be hi.

Now there is an antenna used by MW and SW DX listeners that is something like what you describe (It is known as the K9AY loop). It is a vertical wire loop with the feed point located close to ground. One side of this large wire loop works against ground and is feed by coax via an RF transformer. The other end of the long loop comes back close to the start point and is also grounded, but via a termination resistor. The K9AY is in fact a longwire (according to my first categorization), but a special kind which works against a termination resistor (travelling wave antenna like a Beverage or rhombic) but oriented like a loop. The K9AY provides excellent directional properties. Do a search on K9AY on the internet and you will find a lot of information. If you apply some of the K9AY theory to xmitting I for one will be very interested in hearing the results.

Dave,

You may see Photos of specific 'details' of a SkyWire Loop Antenna.

You may see Diagrams and Drawings of SkyWire Loop Antennas.

But it is not likely that you will see a 'detailed' Photo of an
actual SkyWire Loop Antenna in total.

WHY ?

If you are using #14AWG Insulated Wire that is about 1/8" to 3/16"
Diameter and a SkyWire Loop Antenna that has a perimeter of 270 Feet
to 530 Feet. These photos have to be shot at some distance to get
the entire SkyWire Loop Antenna into the picture. The actual wires
simply will not show up in the Photos.
- - - This is a wire to loop image size ratio of 1:25,000 or more.

This is problem faced by many manufactures of large scale antennas.
- - - Some resort to using 'enhanced' photos that have the wires
drawn in (thickened) to allow them to be visiable to the eye.
NOTE: These types of Photos are usually labeled as 'representative'
pictures of the product.

Hi,

no, just a 12x12 inch gray box, similar to a household electrical system, but it has no connection to the house wiring or anything. Its completely seperate. It only holds the polyphaser and the 0/4 gauge wire connector. Its mounted on a 4x4 post for the back porch directly under the the coax feed for the antenna. The 0/4 guage wire goes to ground directly under the 4x4 post.

I did that - It worked. Pretty noisy though.
I should compare it to my loop... Project for tonight.

I Attached a piece of #12 stranded to a couple of
the sheet metal screws on the roof and then ran
another length of wire to the furnace cold water pipe
to work the roof against...

Try it! who knows.

Some guys wrap their house in a loop of wire and feed it with
twinlead and a tuner.- I dont think that would work with a metal
roof though.

140. matching the loop to 50 ohm coax

Yahoo group: SkyWires
Date: 2003-11-05 21:41:41 UTC
From: desmoface
Topic: 140 Message: 140

Hey kids, so the impedance of the loop at its resonant frequency is around 100 ohms, right? If I'm just feeding it with 50 ohm coax, should I use a 1/4 wavelength section of 75 ohm coax between my 50 ohm coax and the feedpoint of the loop? I'll be using a tuner so that I can use the loop on all the bands between 10 and 80 meters so will it really matter?? Thanks in advance..

Steve,

This SkYwire Loop Antenna is going to be used for Transmission and Receiving both - Right ?

Isn't it possible to make a direct connection of the 50 Ohms Coax and then a making a several 3-4 Foot Coils of the Coax to act as an impedance match.

Hi RHF. It's going to be used for transmitting and receiving on the amateur bands. Well, I think the looped coax will kind of act like a 1:1 balun choking off any stray rf, at least thats what I'm thinking. This worked very well with a triband yagi I had up a few years ago.

I think I'm just going to feed it with 50 ohm coax..My rig is capable of tuning up to a 3:1 match. I'm thinking at the resonant frequency that the antenna was designed for (aprox 3750) I should see between a 2:1 and 3:1 match (approx 100 ohms)..should be no problem for my rig..if it is I can always tweak it with me outboard antenna tuner..I'd need the tuner anyway (probably) for the other bands I plan to work.

Oh well, should be able to complete the project this weekend, gonna be fun trying to measure out 300 ft of 13 gauge 19 strand copper clad steel wire (I'm a one man show) in 30 degree weather LOL..this stuff is tuff to work with - I can't imagine using solid copperweld for something like this.

Oh well...Maybe after I get it on up we can schedule a group meeting on the air?? Would be interesting and I'd be able to get some signal reports and compare the loop to my butternut verticle..Thanks again, RHF..

You can do it if you like. It will not effect
operation on the other bands and you will have an
almost perfect match on 80 meters at the frequency the
loop was cut for. It wont improve the performance that
you will be able to tell it's installed.

NO all the coils will do is choke off RF running down
the outside of the shield of the coax.

Go to Radio Shack and get the black TV twinlead.
(Any 300 ohm twinlead will work at 100 watts out. The
black stuff has held up pretty well for me and has fairly
large conductors as compared to the cheaper stuff)

Twinlead or ladderline will have MUCH less resistive
losses under high SWR conditions than 50 or 75 ohm coax.
IE. More of your power will reach the antenna instead
of being burned up as heat in the coax.

This assumes you are using an antenna tuner.

It is cheap too. In Alaska it costs about $12 for 100 feet.

To answer your question though:

The ARRL Antenna book used to have an antenna called the
"Novi Loop" which used a quarter wave section of 75 ohm
coax to impedance match the 50 ohm coax from your rig to
the 100 impedance of the loop. This was a 40 meter antenna.
You would have to change the length of the matching section if you
were to operate on other bands.

Since you will be operating the skywire on its fundamental
and on higher frequencies, the matching section makes less sense.

Since you might be operating the skywire on non harmonic frequencies,
you may likely see high swr conditions which the tuner will fix as
seen by your transmitter but which will still exist on the feedline.

If you look at http://www.arrl.org/tis/info/pdf/9706057.pdf it has
a write up on transmission lines. Pay attention to the part where
at 28 mhz using rg58 coax and a 6:1 SWR ratio you are loosing 66% of
your transmit power as heat in the coax where using 450 ohm ladderline
you would be loosing only 9% of your power.

Depending on how long your feedline is, and your SWR you could loose
a half to a full S-Unit transmit power as heat in the feedline.

KL7R,

Could using 1/4WL 'section' of 300 Ohm Twin Lead or 450 Ohm Ladder Line allow the use of a 1/4WL 'section' of 50 Ohm Coax Cable to the Transceiver; and provide a 'better' "Match" over ALL the Bands from 80M to 10M ? ? ?

(Coil up the extra Coax if to long.)

80 Meters = 262.5 Feet Full Wave Length

Quarter Wave Length = 65.6 Feet

-OR- Would a Balun be require between the Twin Lead/Ladder Line and the Coax Cable ?

The problem is that a 1/4 WL section is different lengths
on different bands... If it is 65 feet on 80 meters
it would be only 32.5 feet on 40 and so on.

If you have a tuner, It should have a 4 to 1 balun on the
back of it. This should make it easier for the tuner
to load up the higher impedance balanced loop.

If your tuner doesnt have a 4:1 balun on it then it
might be a good idea to get a 4:1 balun to stick on
the output of your tuner to drive the twinlead.
(you could run enough coax to get outside of your
house to the balun then run twinlead from there.)

I just remembered an important detail... In general,
If you are building a multiband antenna you dont want to
have a feedline that is a multiple of a quarterwave long.
This is because a quarterwavelength or half wavelength
of feedline will invert (quarter wave) or repeat (half wave)
the impedance seen at the antenna.

If you take this to the limit, imagine the antenna is acting
like a very low impedance load (a short) then a quarter wave
length feedline will make it act like an open circuit at the
tuner. Likewise for a high impedance antenna will act like
a short at the end of the quarterwave matching section. Shorts
and opens are hard to tune up... Something inbetween is relatively
easy to load up. That is why the rule of thumb. If you

are going build a multiband antenna, you try to aim for non-resonant feedline lengths.

The Arrl Antenna book has a chart in it which gives non-resonant lengths. I chose 55 feet. Others choose other lengths.

Try it. If you have a band which is really hard to tune up, try adding or removing a few feet of the ladder line.

Hey kids, it's finally on the air..My electrician ran my coax and the loop is up and running..She's cut for 75/80 and I originally came up with about 260 ft of wire but I must have measured wrong cause she show's the lowest swr of ~1.7 to 1 at around 3650..my calculations showed it should have been around 3850...Oh well, maybe its because it's not really as high as it should be??..

Anyway, I'm just running straight coax with no balun (except for several loops of coax at the feed point) so I'm pleased so far with the swr readings..As a plus, my old kenwood ts450sat tunes her up on most of the bands without the use of my outboard tuner..although I will use the outboard tuner to get it close...

Anyway, she plays nice on 80..signals that were barely readable on my butternut vertical were 20 over on the loop..but that was to be expected I guess? Suprisingly, the vertical seems to work a little better on 40..I say "seems" because the static noise was a little higher on the vertical and the qso I had with a friend about 10 miles away confirmed that the vertical was a few s units stronger..he was running a dipole so I would have thought that the loop would have been stronger as its also horizonitaly polarized..

Anyway, same with the upper hf bands(10-20)..seems to be a little more noise in the recieve with the vertical..but the bands were in pretty bad shape so It could be that the loop is just that much quieter than the vertical..time will tell..

We should all have a schedule on 80 and hook up for some ragchewing sometime...Im up for it if anyone else is..?? I'd like to thank the group again for all the advice during the construction phase of me bloody loop..YEEHAW & 73's to all..

I saw the same thing that you did about resonant frequency
with the loop being close to the ground. If I recall right
my loop had resonances at something like:

3.3, 6.9, 14.1, 22, 29 mhz.

I tuned my loop to be resonant in the CW section of 20 meters
and use my tuner to tune it on the other bands.

Have Fun with your new antenna. Lets hope the bands get better
soon.

151. Loop Skywire- 3 sided vs. 4

Yahoo group: SkyWires
Date: 2003-11-20 20:43:22 UTC
From: yak458
Topic: 151 Message: 151

What are the real world differences between making a horizontal loop in a 3 sided configuration vs. a 4? On my house lot a delta (3) will be very easy, a 4 sided loop very difficult. 2 story house, very large trees ~ 120 feet away across the back boundry of the lot. I have no problems with the construction, I'm just wondering how a horizontal delta will perform.

Do the feedline requirements change? I have an unbalanced tuner, will feed with 50 or 75 ohm coax, transmitter is one-hundred watts.

Thanks much in advance.

AB9HS

Should work great, they say the its best to get the most area inside of the
antenna so a circle is best, followed by an octagon followed by a square..but a
delta loop should work great...you can feed it with pretty much anything you
want, but ladder line would have less loss...depending on which band you want
to use, you could feed it with a 1/4 wl 75ohm length of coax (x velocity
factor of the coax) for the frequency your loop is tuned for...but if your using it
for multiband operation it wont matter much...Good luck..

Oh yeah, if you use insulated wire for your loop you have to make it about 5%
shorter. Good luck...

YAK 458,

DELTA SkyWire Configurations: If you feed the "Delta" (3 Sided)
from one of the corners: I would suspect that you would get some
directivity on certain frequencies.

SQUARE SkyWire Configurations: If your feed the "Square" (4 Sided)
from the middle of one of the sides: I would believe that you would
have a general Omni-Directional Antenna on most frequencies.

You would have to use some Antenna Modeling Software to have a
better idea of how these two Configurations would perforn on the
various HAM Bands.

My 160 meter loop is a delta loop and works fine. It's
got more gain in some directions and less in others. A
quad would not produce the larger gain lobes and so is
more omni directional. If you could use towers to
support the loop and plastic pulleys at the three
corners you could move the wire around and change the
gain lobe direction. A motor drive would allow
"turning" the loop from inside the shack.

Donnie, if your looking for a ground plane it's real simple. You need a SO-239, 1 piece of coat hanger roughly 19-20" in length, according to where you want to center on the band.
4 pieces of coat hanger approx 5% shorter, for radials.
P.S. if you can find some copper clad for the driven, It soilders better.
I hope that helps.

Hello to all on the list. I'm new to this list have been reading alot of the posts trying to learn all I can about loops. I'm thinking about building one for 80 meters. and I have a question about feeding it with coax or 450 ohm ladder line. which is better if I want to use it on all bands? At my last QTH I had a dipole fed with 450 ohm line and a tuner and I could use it on all bands but I can't really find any info on loops on which is better.

Hal

No Question, you'd have lower loss with ladder line vs coax..and if you use
it on other bands (10-80) you will have greater losses as the swr
increases...that said, the arrl antenna compendium says to just run it with coax
(horizontal full wave loop) without a balun or an rf choke..

I'm running straight coax into my recently completed full wave 80 meter
horizontal loop - but I did put a small rf loop at the feedpoint (4-5 loops of
coax) just for the heck of it..it works great but I'm only running a kenwood ts
450 barefoot with about 100 watts out...If I were to put a kilowat through it -
it would probably heat the coax up a bit because of the higher swr's I'm
seeing on 10-80 meters..

It works great..I was working a guy in the (vp2ebr) in the West Indies
yesterday on 17 meters and he gave me a 5-9 sig report and he, strangely enough, was
also running a full wave horizontal 80 meter loop fed with ladder line..and
he said when he runs the linear , before he switched to ladder line, the coax
would get pretty warm..

Anyway, ladder line is better but coax works fine..good luck.

Steve
kb8viv

P.S. I also worked Italy earlier today on 10 meters on the loop..The loop is
outperforming my butternut vertical on virtually every band..

Welcome aboard. There are plenty of people on this site who will tell you that a skywire is much better than a dipole. This is generally true, as long as you have the room to run one. Space is the limiting factor with a Skywire.

Both ways are fine. RG-58 is light and cheap and on HF
there is not much loss. If you have tuning problems
just cut a little off and try again. Ladder line is no
loss and does not weight very much. Good for extra
long runs and tunes easy anywhere with a good tuner
and 4 to 1 balun.

DB,

While it is not wire; you may wish to consider buying a
Refrigerator "Ice Maker" Plumbing Kit available a Home Depot,
Lowes, ACE, etc. In side this Kit is Fifteen 15 Feet of Copper
Tubing that is Flexible but Ridged when formed. This Cooper Tubing
should easily handle 60 Watts of Power in a properly designed and
constructed 2-Meter Antenna.

Here is a Page-O-Links for Two(2) Meter Antennas:

Hi,

I'm sorry it was Salt creek near Gatesville Indiana.

here is a map.

http://www.mapquest.com/maps/map.adp?
country=US&address=&city=gatesville&state=in&zipcode=&homesubmit.x=16&
homesubmit.y=8

here is the indiana gold prospectors website.

http://www.geocities.com/indianagold/

I only found a few flecks of gold. no real value, but its a lot of
fun. You can prospect for gold during the day and star gaze at night.

Sorry to be way off topic guys...

169. I just installed SETI@home on my computer.

Yahoo group: SkyWires
Date: 2003-11-29 19:43:48 UTC
From: exemptfromlife
Topic: 169 Message: 169

In a nutshell, I've installed a piece of software on my computer
that
acts like a screensaver, and only activates when the computer is not
in use. It grabs data from a radio telescope and chews on it looking
for radio signals from outer space. The results of the data analysis
are then sent back to UC Berkley for further analysis if necessary.

If my computer helps find ET, then I will be named as one of the co-
discoverers, if not, then I have a much more interesting screensaver
running than a bunch of warp-speed stars flying by.

Here is the link to a more detailed explanation if anybody is
interested.

http://setiathome.ssl.berkeley.edu/about_seti/about_seti_at_home_1.htm

thanks.

170. Xtra long loop

Yahoo group: SkyWires
Date: 2003-11-30 02:20:10 UTC
From: Hulen Smith
Topic: 170 Message: 170
Attachments: 1 described; binary payloads are missing from this source WARC

Hello to the group,
Been reading the mail here with some interest for a few weeks now. I've decided to throw out to the group my property dimensions. What I have available is about 800' by 200', obviously not square. In the interest of putting up as much wire as I can in order to have mulitple wavelengths, I would need to use all the footage. What is the consensus of what the signal would look like. Seems to me it would favor the long sides as would a dipole but I'm not sure due to the numerous wavelengths. I'm operating a skywire now using a fullwave loop at 7.150 mhz. I want to operate 160m. Would the extra length be worth the effort ? If I can get a couple more db as opposed to a single wavelength then my answer would be yes. But then I'm not sure what I'll get, however it's fun to read about and worth experimenting with. That's the part that makes ham radio a hobby for me. It isn't so much the PTT circuit. :))
Any opinons ?
Thanks for any input

Do you know how to make a dual band 2m/440 twinlead jpole?
Seems like it could be done. Arrow antennas makes a dual
band jpole type antenna using arrow shafts. I bet with a
third wire 6 inches long you could make a 144/440 dualband
jpole.

Wanna have some fun?

Download an an antenna analysis program and try it out:

I use MMANA http://www.qsl.net/mmhamsoft/mmana/index.htm

There are examples in there for big delta loops for 160 meters

You could experiment with the shape of the loop on your lot
it could be a rectangle with corners at each corner of your lot
or it could be in the shape of a diamond (rhombic) with corners
in the center of the sides of your lot or maybe you will find
some other shape that works in a direction that you want
to favor.

What direction is the long side of your lot alligned with?

The loop will tend to have more gain along the longer wires
like a ling wire. With the shape you have I bet a rhombic
shape would be the most gain on the high bands.

I went ahead and made a couple of MMANA files for your
800x200 foot lot.

Check out:
http://groups.yahoo.com/group/SkyWires/files/kl7r/

Load them up in the MMANA antenna modelling software
and experiment

I found out that the rectangular loop worked best if
fed in the center of the shorter side. If you feed
it in one of the corners the gain goes down a bit and
the patter becomes more omnidirectional.

I found out that the rhombic shape has a bunch more gain.
Something like 12dBi on 160 and has good low angle radiation
on the rest.

If you put it up, I bet you will be heard...

174. Off-Center Fed SkyWire Antenna ?

FO&A,

What would be the Advantages of Disadvantages of a
SkyWire Loop Antenna that is a Non-Center-Side Fed
or a Non-Conner Fed; but is FED "Off-Center" on one
of the Sides ? ? ?

A "One Wave Length" SkyWire Loop Antenna of 529 Feet:
(Layed Out in an Isosceles Trapezoid Shape)

* FED End Length = 106 Feet

* * Feed Point 35 Feet from the Corner
= = = 1/4 WL = 40M
= = = 1/2 WL = 20M
= = = 1 WL = 10M

* * Feed Point 71 Feet from the other Corner
= = = 1/2 WL = 40M
= = = 1 WL = 20M

* Length of Sides = 145 Feet Each

* Far End Length = 132 Feet
= = = 1/4 WL @ 160M

? ? ? HOW DOES THIS SHAPE AND SIZE MODEL OUT ? ? ?

I run a full size 160 meter loop skywire and it works
great! I am planing on putting up a three times 160
meter loop, thats 1,590 feet of wire and feed it with
450 ohm ladder line. It should be intersting to see
how well it does.

I've been on and off SETI for a couple of years now. For a different
angle on it, you can have several people/computers running SETI as a
team to pool efforts. Perhaps a "Skywires" team?

The only thing it will effect is where the gain lobes
are on any band above the lowest band it's built for.
If you use plastic pullys at the corners and a rope
attached with an insulator that would allow you to
pull the feed point several feet one way and the other
you can point the gain lobes in the direction your
intrested in for which ever band you want to do that
on. For the loop on it's design band.. say 80 meters
pulling the feed point around will make no diffrence
as the signal is going almost stright up which on 80
meters works fine. On 20 meters and above you get gain
lobes taking off at low levels and pulling the feed
point a few feet eather direction can make a big
diffrence.

HI:

If you have a full wave length loop for 40M up already and you want to try out 160 M. I suggest feeding the whole thing as a vertical antenna against ground. The feed line (coax or open wire line) would be the vertical antenna, the 40 M loop would be a "capacitive hat". You will then have to provide a ground rod minimum with radials as you want to increase efficiency.

When you get this going you will most likely use this arrangement for transmission only and use a magnetic loop antenna for reception.

At first when I heard about this I thought it sounded kind of cool, then I thought it sounded too "X-fileish", then I decided, Well its possible something else is out there, and within listening distance. Plus I do let my computer run during the day when I'm home, so I figured it was a win/win situation. At worst, I have a really good screensaver now that actually does something.

I just thought that some other people may not be aware that this existed, and it had to do with radio communications (sort of), and anybody reading this has access to a computer.

thanks.

The narrow ends would point east and west with the broad sides north and south. South doesn't help me much as I'm on the Texas Gulf coast but any other direction would be lots of area for me !! :)
>I went ahead and made a couple of MMANA files for your
>800x200 foot lot.
Thanks for the link to the modeling program and the files you created. I hope to have some time this week to play with that some.
Thanks also for your comments. I found them to be very interesting indeed !! :) I've always thought about a rhombic but don't like the idea of one or two band use and directional or bi-directional signal. Besides I think a rhombic would have to be very high in order to be effective, just AWAG. I know that isn't what you were saying though. Your comment was about a loop in the shape of a Rhombic and that's what was interesting.

Hello Hulen,
I use a 75 meter Delta Loop and a 1/4 wave inverted L antenna for the 160 meter band .
I like to be able to just flip a switch or switches to change bands .
I don't want to need to unscrew a PL259 and short it to feed the 75 meter loop on 160 .
The inverted L antenna is easy to build and works well .
For more info check out this Web Page .

I had a 160 meter full wave loop skywire . Then I tried making it 2 wavelengths and then 3 wavelengths .
It was my experience that it was not worth the trouble to make the antenna any larger than one wavelength , it didn't work any better on 160 .
I also found it was much easier to change the frequency rather than changing the antenna size to do the testing . By increasing the frequency I did some tests with up to a 10 wavelength loop .
By the way 2 wavelengths presents a high VSWR the loops need to be an odd multiple of wavelengths such as 1 , 3 , 5 , etc.

I also did some experiments with the 160 meter inverted L antenna .
I tried a 1/4 wave length inverted L antenna , a 3/8 wave length inverted L antenna, a 1/2 wave length inverted L antenna , and a 3/4 wave length inverted L antenna all on the 160 meter band .
Once again I found that it was not worth messing with making the inverted L antenna any longer than a 1/4 wave length .
Many times the 160 meter 1/4 wave length inverted L antenna out performs my 75 meter loop skywire on the higher bands such as 6 mtrs , 10 mtrs etc.

Thanks Ace for your comments. I did know about the odd muliple wavelength. I can do 3 or 5 wavelengths here but I did guess that I wouldn't be able to see an appreciable difference in that compared to a single wavelength. Even if it were 2-3 db difference, it's hard to justify the added costs and work envolved and who really can see a 3 db difference in signal ? That's not even an S unit.
I'd like to have an inverted L but all I've read about those is you need to be high up in the air. I'm limited to about 40' here. I lost my tower about 15 yrs back due to "quick out of nowhere" storm. I won't be going up with anything higher but will try an inverted L if some of you get good results with the appex at 40'.
Anyway Ace, good comments, thank you again for your take. Oh and the frequency thing was a good one. I've thought of it but then forgot again. I can claim to have some good ideas but then I loose them as rapidly as they come !! LOL!!!!!
Cheers !!

Topic: 184 Message: 185

The difference in adding length to a full wave loop is not seen in
gain, but take off
angle of the largest lobe.

w4rnl goes in to much more detail on his website (www.cebik.com), but
in general a
full wave loop is a horrible antenna for DX, but great for close in
contacts. if you
extend the length
of the antenna past 1 wavelength of intended use, the take off angle
becomes lower
and increases the chance that can work DX. Example: if you use a 75M
loop on 75M,
you will get plenty
of local HAMS and not much DX. If you use a 75M loop on a higher
band, like 20M,
you will get stations from much further out. If you build a 160M full
wave loop, the
DX on 80M
increases.

Hope this helps.

angle of the largest lobe.

w4rnl goes in to much more detail on his website (www.cebik.com), but in general a
full wave loop is a horrible antenna for DX, but great for close in contacts. if you
extend the length
of the antenna past 1 wavelength of intended use, the take off angle becomes lower
and increases the chance that can work DX. Example: if you use a 75M loop on 75M,
you will get plenty
of local HAMS and not much DX. If you use a 75M loop on a higher band, like 20M,
you will get stations from much further out. If you build a 160M full wave loop, the
DX on 80M
increases.

Hope this helps.

Hi All,
I am using a 1/4 wave , 160 meter band inverted L antenna .I get
good results with the apex on my tower at about 40' maybe 2 or 3 feet

lower . I have the end tied in a tree about 50' above ground .
I have worked all 50 states and several countries with it on 160
using 100 watts . I am not much of a DXer.

188. Art Bell's Band Blaster

Yahoo group: SkyWires
Date: 2003-12-02 23:28:14 UTC
From: rocketradio2002
Topic: 188 Message: 188

After hearing Art's fantastic signal on 3.840 even during poor conditions, I really want to build something similar. A search turned up this group and the articles on eham. Lots of excellent information. Thank you. However I have one question that hasn't turned up an answer yet. On Art's series of pictures it shows a double loop that apparently is 6 foot lower from the top section. How are the two different sections fed together? Also it seems that there seems to be a point where additional height doesn't gain that much in performance.

Thanks for any input.

George

Thanks for joining.

I've seen the photos of this double loop that Mr. Bell has. I can't figure out how its fed either. It looks pretty cool. I don't know If I would want it wrapped around my house/compound as he does. I would think that would be asking for electrical interference.

It could be that the coax center is attached to one end and the braid to another, or that it is actually just one big loop that spirals up with two twists.

I did read about his loop creating an electrical charge. He seemed to think it was being generated by something other than static electricity. I tend to believe the logical, earthly explanations first. I think since he is in the desert, and its dry, that there is a lot of static build up, even on a windless day. There is still dust in the air.

If you have the room, and don't mind spending the cash to put up 8 or so poles, then I think it would be a great idea.

Have you tried writing him to find out how his loop antenna is fed?

Thanks.

I have started work on a very large loop and hope to
have all the required supports in the trees and paths
between them cleared soon. I have 1,590 feet of wire
measured and rolled up ready to start pulling up
between the trees for a three times 160 mter loop. I
hope to be able to get some low angle off of it for DX
on 160 meters!

The original loop was a single wire:
Check out:
http://www.candlewater.com/3830/artsloop/

From what I have seen it appears that he was picking up a lot of
induced current in his area (400v) I bet he put up the second
loop below the real antenna above to shield his top loop
from the power grid 60 HZ induced current?

Thanks for the info! I think that you might be correct on the lower loop being some type of "shield". I have downloaded and printed many many pages of loop antenna designs and none of them refer to a lower loop in any of the plans. I have seen some reference to a counterpoise being used on some designs, but they were mainly some type of ground rod near each corner of the loop. But why would a balanced antenna need a counterpoise? I'm figuring out this weekend where on the property to put the loop. I have about three different areas where I could place one. The closest being a 3 acre field near the house, but would still require about a three hundred foot run of coax or ladder line to make it to the shack.

A few accumulated comments about Art Bell's loop....

When Art first spoke about his loop on the air on his radio program, I looked at the pictures of it he had on the web site. It appeared that he had both loops fed in phase, though the lower loop is slightly smaller in total diameter. In looking at how a normal antenna would act, the spacing of the two elements would act as if it were a larger diameter element than the wire being used. In essence, it would be as if he had put up a five foot diameter tube as the radiating element. This would tend to make the antenna more broadband... that is, it would allow using it over a wider frequency range with reasonable swr.

I'm still not sure how this really works out in practice, particularly for a horizontal loop. As (at most frequencies, anyway) a horizontal loop isn't necessarily resonant on the frequency of interest, the effect may not be the same as a dipole with a second wire spaced some number of inches below the main wire. With the dipole, if it were cut to 75 meters, with a single wire the swr may be acceptably low for a 300khz segment of the band, but with two wires of the same length, spaced 6 or 9 inches apart, the swr may be acceptable for 600khz. With a horizontal loop, the action may or may not be the same. Somehow I don't expect it would provide a counterpoise or reflector, particularly as both wires are connected together, and they are so close together at HF frequencies. Besides, a horizontal loop at it's fundamental frequency is pretty well known to be a "cloud burner" anyway, so I can't imagine why anyone would want to increase this effect. A horizontal loop is generally a pretty quiet antenna to begin with, so I'm not sure how much any shielding effect would help. Still, what effect his second wire has at this point is still a mystery to me.

Currently, I have about a 800' (to 900') horizontal loop at an average height of 38 feet, and it seems to be pretty effective. When I put up the supports, I prepared it to be able to put up a second (or even a third) wire below the first at 5 foot spacings. I still need to clear a corridor through a couple of trees before I put up a second or third wire to find out what the effect really is. I don't think it would be a fair test to add even a second wire right now, as one leg of the roughly rectangular loop sort of zig-zags through three trees, and it would be nearly impossible to maintain decent spacing with a second wire through this area. However, once I get the path through these trees cleared, I'll be characterizing the single wire first, then pulling up the second wire, and even possibly a third. Then I'll at least have some empirical data on the effect of the additional wire.

Art has also mentioned a charge on the loop, though I don't recall if he specified whether it was DC or AC... I'm assuming it is a DC voltage, as I don't recall seeing any AC powerlines in the immediate vicinity of the loop, from the pictures he had on the web site. Given his location in the high desert, with relatively low humidity and near constant wind, it is definitely possible that this is a static charge generated by wind across the wire.

Initially, Art was indicating he was getting a really high gain figure from the antenna, which he didn't expect. In thinking about it, depending upon the actual loop length and the band he was talking about, he could see considerable gain, particularly at higher frequencies, where the loop has the correct number of multiple wavelengths to provide a high gain lobe in a particular direction.

I'm not in the shack right now, or could provide more accurate number of the length of my loop, and also provide a brief list of how it looks at higher bands. Perhaps one of these days, I'll model it and see what the eznec has to say about it....

Thanks

I would definately avoid the 300 foot coax run
in favor of ladderline or twinlead or windowire
to avoid losses in the feeder.

196. Folded full wave loop question

Yahoo group: SkyWires
Date: 2003-12-09 01:12:11 UTC
From: Jim Dunstan
Topic: 188 Message: 196

Hi all:

I am interested in transmitting/receiving with a loop antenna (for 20M) from my apartment balcony. I am not thinking of a small tuned loop, but a full size loop that is coiled into 2 or 3 turns. Here is what I have in mind:

A 20 M wavelength is approximately 65', which would represent about 16' for side in a square configuration (too big for my balcony). If I arrange the wire into a 2 turn loop the square would now be about 8' on a side and a 3 turn loop would be about 5' on a side. I could barely manage an 8' square .... but a 5' square would be great. I would feed it with about 8' of open wire line to my antenna tuner. Its orientation would be vertical and could be rotatable.

I wonder if anyone has tried this kind of arrangement? What opinions are there about what one might expect in performance from such an arrangement Re bandwidth, directionality, ease of loading, etc.

This would be a minimum type skywire .... hi.

198. MARS Loop antenna link.

Yahoo group: SkyWires
Date: 2003-12-09 17:15:15 UTC
From: n4zou
Topic: 198 Message: 198

I just found this link and thought it very intersting for the group.
http://www.almars.org/Loop%20Final%20D.pdf
I run a 160 meter loop here with 450 ohm ladder line feed. Of note here is the use of a counterpoice under the loop. I do not use a counterpoice and never thought one would be required. It would be very easy for me to add one using nail up electric fence insulators and aluminum electric fence wire. I think the reason for use is to make the loop even more of a cloud burner than normal without the counterpoice. In this situation I would think you would want the counterpoice 5% larger than the loop element. This would produce a two element beam pointed stright up! I might be incorrect in my thinking here as the elements would be spaced so narrow. The other possability is that the counterpoice is about the same size as the main loop and causes the loop to mushroom and have gain out the sides and not be as much of a cloud burner. I am getting a headache thinking about it right now! I think I will add a counterpoice of 565 feet of wire as I have 530 feet up in the loop. I can try it for a while and then cut out the extra 26.5 feet and see what happens...If anything.

You can have a multi-turn loop but you must have a capacitor on each turn that is tuned for the frequency you are going to use. You start out with small receive type verable capacitors and tune the loop using an SWR analyzer or QRP power and a SWR meter. After you find the point where the loop is showing a low SWR and all the capacitors have the exact same capacitance you replace them with high voltage door knob capacitors of the same capacitance except for one on the first turn connected to the feedpoint where the center conductor is attached. You will need a capacitor rated for very high voltage here. These small loop antenna's are not very popular as there hard to setup and larger than a simple single turn small loop also known as a ARMY LOOP. MFJ still sells them and units from AEA are still to be found on the used market. You may also make your own. It only requires one loop turn and one capacitor. The ARRL antenna book details how to build one.

The carpet loop looks interesting:

You would need a high voltage cap or a good tuner
or reduce power some.

http://mysite.verizon.net/vze20h45/radio/carpetloop/carpetloop.html

I had a lot of success with oversized slinkys...
I never tried to arrange one into a loop
That might be a fun experiment.

What the fellow is calling a counterpoise is really acting
like a reflector which I imagine causes the antenna to work very
well as an NVIS (shoots straight up for close in work) antenna
on 80 meters. I imagine the reflector would have less effect on the
higher bands.

I dont think that a loop needs a counterpoise.

It is a balanced antenna like a dipole and so
half of the antenna works against the other half.

A counterpoise is needed when you endfeed a random piece
of wire. I dont think it is needed when you feed a loop.

I base this statement on the experience of getting
PSK and other digital modes working at my station.

When I load up a semirandom antenna (like a 32foot metal vertical)
against my station ground (which is acting like a counterpoise), I
get a lot of rf in the shack. My soundcard speakers are the
canary which let me know that I have high rf levels floating
around on my audio lines. When I tune up my loop, I rarely,
and only on certain bands, hear rf on my soundcard speakers.
I think that I have feedline length problems on those bands
I have a tuner which allows me to tune my ground (counterpoise)
so I am always able to remove rf feedback from my speakers.

When a windstorm comes and my loop breaks and half is laying on
the ground you can bet that I know right away because the balance
is gone and my son comes in the shack worried that I have popped
his subwoofer...

Wow.. this is a lot of work...Just measuring out the wire took a long time..now if the weather will co-operate with me..the high temp. for tomorrow is only going to be 21 degrees F.
The funniest thing is that a 40 meter loop is the only antenna I can put up... I have trees on three sides in the back yard but its only 65 feet E-W and 55 feet N-S..So hopefully I'll have the loop up this weekend..

There are three ways to do it. Use the coax as a vertical element by shorting the coax at the point where it connects to the tuner and hook it to the random wire post and the tuner ground is connected to a ground system. This is a pain and provides poor results unless you have an extincive ground radial system. If you had that already you would not be installing a loop skywire! The second way is to put an insulator in the wire on the other side of the feed point making it a folded dipole. It's no longer a loop now so you don't really want to do that! The third and better way to do it is to build a folded loop. In the case of a 40 meter loop the size would be 140 feet. A full size 80 meter loop is 272 feet. This is a diffrence of 132 feet so to operate on 80 meters we need to basicly add 132 feet of wire somewhere. This is where you build a section of ladder line with the wire seperated about 6 or more inches appart. 450 ohm ladder line spacing is too small to work properly. To make the folded part of the loop to add the missing 132 feet of wire make the 6 inches (or more is better)wide ladder line 70 feet long. Calculations show we need 66 feet but nothing ever comes out to exact lengths for antennas so we are making the special feed line 4 feet too long. Now grab some 50 ohm coax which can be any length and starting at the very end attach the coax to the feed line. Move the coax attachment point up the line a little at a time untill a good match is found. You may now attach the coax to this point with solder and cut off the extra feed line. The feed line adds nothing to the gain of the antenna and do not expect the 40 meter loop to work as well as a full size 80 meter loop. Dont let this discourage you! It will still work and you will get good signal reports. Also the low SWR bandwidth will be narrow as compaired to a full size loop. If you can bring the end of the ladder line to the back of the tuner where it can be attached to the 4 to 1 balun inside just tap the point where a 200 ohm impedance can be found. You also could use 450 ohm ladder line. Just find the 450 ohm match and connect it there. Hope this helps!

A full wave 40 meter loop is mathematically a half wave loop on 80...should
be able to use it with a good antenna tuner...

Hi,
I like the K.I.S.S. method . Try it this way . Not knowing the exact frequencies involved . ie the design Freq of the 40 meter loop or the Center Freq you want on 80 meters . I used 7.15 Mhz and 3.75 Mhz respectively . Using those Frequencies you would feed the 40 meter loop with 64 Feet of 450 ohm ladder line then tune it up on 80 meters using the tuner . Since you will be using a tuner it should work fine across both bands . Just consider the ladder line to be part of the loop . The ladder line will not radiate so it will not work as well as a full size loop on 80 meters.

Hi Hal ,
Sorry I gave you some incorrect data . To make your loop play
on 80 meters you will need to adjust the length of the 450 ohm ladder
line . Here is some data to consider on ladder line.

For 80 meter antennas
[Avoid 66, 135, 190 ft]

For 40 meter antennas
[Avoid 32, 64, 96, 128 ft]

214. LDG RT-11 and sky loops

Yahoo group: SkyWires
Date: 2003-12-15 13:28:07 UTC
From: Tim
Topic: 214 Message: 214

Hello all -
I just switched antenna setups and cannot figure out what is wrong. If anyone has an idea I'd love to hear it! Prior to changing I had a wire loop around
my roof (roughly 200 feet) connected to ladder line which was connected to an LDG 4:1 balun and
then the LDG AT-11. I used it for 2 years and it worked extremely well EXCEPT the
ladder line caused RFI which interfered with my phones and alarm system - even after judicious use of chokes etc.....SO I decided to redue the loop. I thus mounted an LDG RT-11 outside. I tested the RT-11 with a dummy load before mounting and I believe it is working fine. My loop runs to a 1:1 balun and then to the tuner. The tuner has about a 50' run of coax to the shack. I have a 756ProII and have the LDG remote control box in my shack connected to the Icom. Using an MFJ meter I measure SWRs of 5.2 down to 1.8 on the frequencies I like to work - normal for a loop. However, I cannot get the tuner to show an SWR on the 756ProII SWR meter below around 4 for 40m and 20m. In general the SWR meter seems to go off the charts before it even gets close to 4 or so. Any thoughts? I believe a 1:1 balun is appropriate for this kind of loop with coax - ie a current type vs a transformer type - maybe I am missing something there? I used the 4:1 previously because of the ladder line. BTW the good news is that the RFI is gone!
Any thoughts would be appreciated. Thanks folks.

215. Minimum height for a 40m Skywire?

Yahoo group: SkyWires
Date: 2003-12-16 14:29:10 UTC
From: JimMcSkate@aol.com
Topic: 215 Message: 215

Last night I finished putting up my 40m Skywire... of course to call it a "Skywire" is a bit of a misnomer - my max height is about 20 feet.

As advertised, it tunes on its fundamental at 1:1, and tunes via transmatch as a vertical on 80 when I short the feedline. I can tune it on all the bands I use... however either the bands were very quiet last evening, or the antenna doesn't work well at this height.

The question: At 20 feet, how can I expect this antenna to perform? Or better yet - can I expect this antenna to perform at all?

Many thanks,
Jim McAward

Jim -
I've used a Sky Loop at about 22 feet for 2 years in Arizona. I've talked on 100 watts all over the world with it. I operate 99.9% cw, but I have talked SSB from Australia to France. So yes it works! Also, for me the bands were very quiet last night. The low noise level of the loop can also throw you at first.
Now I have a question for you: could you describe in exact detail how you constructed a "short to work 80m" - I'd like to know about it. I can work 80m with the Sky Loop as is (random length is about 200 feet), but it's not real great on 80. What did you do here?

Tim,
Thanks for the vote of confidence on my 20' Skywire. I'll play more with it over the next few nights and see how it goes.

As for the shorting details: I feed my loop with 300-ohm RadioShack twinlead... it's cheap, it works, and as I only get up to about 100 watts it's fine. At the shack end of the twinlead, it's connected to a dual banana plug, again from RadioShack, which plugs into posts on my transmatch.

The dual banana plug is meant for some type of test equipment, and has a pair of matching sockets on the top. To get on 80m, I plug in a shorting jumper to the sockets, then let one of the plugs "float" away from the matching binding post on the transmatch.

I am only now realizing how convoluted this sounds - but it's really easy to do. I'll send a picture if you need me to.

If you are using coax, you'll have to wire something up. I'd use a short piece of RG-8 cable with the outer braid removed - you attach a PL259 to one end and an SO239 - shorted - to the other... the inner conductor carries the juice, and there's no outer conductor!

Good luck!

Tim,

I got the design details from an old article in QST (November '85) called "The Loop Skywire" (by Dave Fischer/W0MHS)

For the band(s) under the fundamental loop frequency (i.e. 160 and 80m on a 40m loop), the author describes using the feedline itself as a vertical element with top-hat loading... this is done by shorting the feedline at the shack end, then driving it the same way as you'd drive a random wire. You need a tuner for this - but it does load nicely. As for reception? The jury is still out on that question ;-)

If you're an ARRL member, you can get this article from their archives - just search for keyword "Skywire"... if you are not a member I will figure out how to get you the details.

Have a great day,
Jim

My experience with my 80 meter loop is that it doesnt like
to take power on 160. So your 40 meter loop would probably
have the same problem taking power on 80.

When I want to load up on 160, I short my ladderline
together at the antenna tuner and use the ladderline/loop
combination as a "toploaded vertical" sort of random wire.

Others have solved this problem by breaking their loop
in half opposite the feedpoint and either placing a jumper
across the break for normal loop operation and opening
the break for "dipole like" operation or by placing a
trap where the break would be tuned for 80 meters in your
case or 160 meters in my case.

Here is a link to a program which helps you create traps
from just a hunk of coax:

Hi Jim & Tim:

The idea is pretty simple and effective. I used the same system on 160M years ago. In my case though the antenna wasn't a horizontal loop but a 100' inverted Vee antenna mounted on the roof of a 2 story house. I used 300 ohm TV feedline to the shack in the basement of the house. I used a tuner to feed the inverted Vee on 20M, 40M, and 80M. I was using an old Heathkit DX100 AM Xmtr.

I also operated 160M by shorting the feedline, in effect making the 300 ohm feedline a single wire (in effect a vertical) going up to the inverted Vee which in turn acted as a capacitive hat. I used the copper pipe in the basement as the ground system. I had a great time that winter working the "Farmers net" on 160M every morning (before milking time hi).

Everyone was on AM on the net at that time. It sure sounded nice and all the signals came in great.

First night with the 40m Skywire, and it works! KL7R previously that his 80m loop would not take power on 160, and speculated that a 40m loop wouldn't take power on 80, which is the case for me. (I have to run the antenna in the vertical-with-capacitance-hat configuration to load on 80.) I made one sloppy contact on 80m phon this way, but had much better performance on 160... and for some reason my loop loads on 160 without the tuner - my SWR is around 3:1, which was fine for my tube-final TS-820. I had S9 reports in Hershey, PA and in Woodstock, CT running 75 watts. The antenna loads (also without the tuner) on 40 (1:1 at 7.200!), but needs the tuner for 20, 15, and 10. Either those bands were very quiet last night, or the antenna doesn't hear well... I'll experiment and post the results.

OK -
Just curious....I am experiencing a pretty quiet 20m band out here in Arizona as well - so I suspect it's not an issue with your antenna :-) BTW Long Beach area used to be my old stomping grounds 30 years ago. I bet a lot has changed since then (except Nathan's hot dogs)!

I dug into MMANA a bit, thanks to a previous post on this list. My 40m loop, at a 20' average height, is a cloudburner (NVIS) on 40, but has a lowered radiation angle on the higher bands. NVIS is not a bad thing - I've made some solid contacts within a 600 mile radius, including one CW mobile in Illinois.

This morning I bagged Italy on 10m. I performed some a/b tests between the loop and a 10m vertical - the noise floor was much lower on the loop than on the vertical, for the same received signal strength. While one contact does not tell a whole story, it seems to support what I've read elsewhere about these loops.

I'll keep playing, I mean "Experimenting"! (This is science, not play... or so I tell my family ;-)

Jim -
One thing I have noticed about my loop which I think we should allocate to "the great mystery of propagation": it often communicates to locations that my NecPlus model says it should never reach! Guess that's what I love about ham radio - always a mystery to me!

From: exemptfromlife
Topic: 230 Message: 230

Yesterday my wife noticed that my skywire came down sometime during the week. Our dog had gotten himself all hung up in the trout line I used to hoist up one of the insulators.

Just as an informal poll, what doe most of you use to secure your skywire? trout line, wire, etc.?

thanks.

You want to use some good quality uv resistant rope, available from places
like davisrf.com...fishing line will eventually, well, do what it did to
you...good luck..

HI,
I am using wire right now , I have used yellow rope but it rots
after 5 - 10 years depending on the diameter .
But I talked to a guy on the radio that told me, He uses Weed Eater
line from Wal-Mart . I checked it out and you can get a giant roll
for less than $20 .
This guy told me that he hooked one end to the bumper of his truck
and pulled his antenna up and that it had been up for over 5 years .
The stuff is very hard to break . He said he is using clear and that
it is invisible and looks like the antenna is floating in the air .
When I went to my local Wal-Mart store they only had purple and green
. But they did have at least two different diameters .

I use teflon-insulated 16 gauge wire on the supports for the 40m loop (and for the loop itself). The stuff has a pretty good tensile strngth, is (or should be) UV-immune, and the teflon keeps the support wires from binding in the trees.

Two corners are on springy 8 foot sticks (1.25 square stock) attached to structures; one corner is attached to a sturdy maple, and one is tossed over a treetop and attached to a tensioning weight. The wire floats in the insulators, and I rely on an old sash window weight to maintain tention.

Had some pretty good results on 15 today, and 20m was hopping tonight... but family commitments kept me from chasing some DX.

Have a great day, and get that wire back up soon!

FO&A,

The Weed-Eater Line sounds like a Good Idea . . .
- - - But, it is a Mono-Filament and can be easily damaged
so that a Break will occur at the point of the damage.

FWIW: The UV resistant woven ropes usually hold up well
and are highly resistant to "Breakage" type Faliures.

IMHO: Parachute Cord (Shock-Line) is relatively small and durable.

* PARACHUTE CORD. (The Real Thing) Heavy Continuous Filament
Nylon Shroud Covers Seven Inner Nylon Cords. Rated at 550
Pound Test. Usually available in Olive Drab, Black, White, ETC.
Size: 300 Foot Spool at about $20.

* GI STYLE UTILITY CORD. (Cheaper Look-A-Like = Works OK)
Flat Woven Camouflage Colored Nylon Cord with a Poly Core
about 3/16" Diameter. Size: 100 Foot Hank at about $4.

? ANY ? OTHER ? SUGGESTIONS ?

RT,

Mono-Filament? -or- Braided ?

IMHO: One of the new Spectra Fiber (Micro-Filament) Fish
Line that is Fully Abrasion, UV and Chemical Resistant;
would be a Good Choice.

I would NOT use the cheaper Dacron Braided Fiber Fish Lines.
- - - Or, a Mono-Filament Fishing Line.

AFAIK: The big 'problem' with the using Fishing Lines as
Antenna Structural Guides is their "Small Size" and the
hard process of handling them.

FWIW: This is WHY I suggest using the Parachute Cord for
its 'ease' of handling; relative small size; high strength
and durability; and basic low cost.

NOTE: I were trying to build an OutSide "Stealth" Antenna
using a "Sky Blue" Colored #24 AWG Hook-Up Wire then Fishing
Line that is "Nearly Invisable" would be a major consideration
as part of the design and construction process.

At 09:45 AM 12/21/03 +0000, you wrote:

Re: discussion about support cable. I have had wire antennae of various kinds up in the trees out at my woodlot for almost 30 years. I use a good quality tight weave nylon rope 1/4'-3/8" (being able to stretch a bit helps). I have a small shack out there and I keep a fishing pole with spinning reel (closed face type) on hand. I also keep a sling shot on hand with a number of 3/4 oz lead weights. All of this is in case one of the halyards lets go.

When a halyard lets go I then put my re-stringing technique to work. I take the rod/reel out and place it in the vicinity of the target branch. I put it on the ground with the tip pointing in the general direction of the target. I release the bail on the reel, put the weight (with a colorful red ribbon) in the sling shot and then shoot it over the desired branch. I have pretty dense bush so the hardest part is finding the weight since the monofilament is all but invisible. This is where the colorful ribbon comes into play. I have tried dipping the weights in some kind of fish or gravy etc and get my beagle to sniff it out. He can do it except he is more interested in rabbits. Many of the halyards are up almost 50'.

All told I have about a dozen halyards up in the trees for the various wire antennae. To minimize the breakage and the time it takes to put them up again I do some simple maintenance twice a year. The result is that I often go by a whole year without fixing any of them. Here is how it goes:

I find that the quality nylon rope lasts many years between replacements. However, where the rope goes over the branch there is considerable wear/abrasion as well as degradation with moisture. This area of deterioration is usually no more than a foot in length. It doesn't make sense to replace the whole rope. So I lower the rope, splice in a short length at the abrasion point, then haul it back into place. I do this once a year .... usually in either the fall or spring when the leaves are down and the branches and ropes are more easily seen. This also the time of year any changes are made.

I have each halyard tied off at the ground level. To lower the halyard I use what I call a 'working rope'. I untie the halyard, attach my working rope, then lower the end down to the ground. I examine the halyard, find the critical section, then splice in fresh rope, and then raise it back up in place. A pair of binoculars is also handy to examine halyards when still in place.

I have tried different kinds of rope/material and have not found anything that stays up more than a couple of years. Regular maintenance is essential.

Sounds like you have a lot more experience in wire's than I..but a trick that
works pretty good is using plastic plumbing tubing...I ran the rope through
the tubing and haul it up into the tree..so that the tubing is taking the
abrasion...so far so good..

The guys around southern New Mexico swear by hay bailing twine. It's readily available, try hardware for spools to a couple of hundred feet or farm supply for spools of a few thousand feet. It has great strength, is UV resistant, relatively cheap, compare to other suggestions, color is orange and it's flexible and easy to work with. Long life, many antennas have been in the sky for 5 - 10 years, needed no work.

Very interesting. When I first read your comment I thought ..... yeah,
but how do you get the tubing up in the appropriate location. Then I
thought .... "well wait .... maybe that has merit". You may be
right.... next time I will bring down the halyard long before
deterioration and note where the wear is taking place. I will run the
tubing over the rope and bring it over the abrasion portion then tape it on
either end to stay in place. I will then pull the halyard back up until
the tubing is over the branch .... and it should be in the right place.

Thanks for the idea. I'll try a couple of them in the spring.

Hi Jim..What I did was slip the tubing over the rope, attach my marine
pulley, and when I pull it up into the tree the pulley kind of holds it in
place..you can even tie a not in the rope at both ends of the tubing..but I just used
the pulley, thinking that if the tree grows around the tubing, I'd still be
able to lower the supporting rope through the tubing (if something jamed up the
rope in the pulley or to replace the pulley)..I figured the rope wouldn't last
too long without some protection from abrasion..

I found the tubing at a local Home Depot/Hardware store, it was like $5 for
twenty feet..I believe its used to run the water to ice makers in
refrigerators..worked perfectly.. If It weren't dark here I'd email you a pic of the setup

244. 40m prop or my loop change?

Yahoo group: SkyWires
Date: 2003-12-25 16:45:07 UTC
From: Tim
Topic: 244 Message: 244

Hi all -
I recently was off the air for about three months. for three years I had a loop up around my roof that worked quite well on all bands. A few weeks ago I replaced the wire with a longer wire/same thickness (maybe 20 feet longer - it's now about 200 feet) and I raised one corner of it to about 30 ft on a mast that I installed. I also created a much shorter coax run. I run about 20 feet of coax to the outside wall of my house to an LDG4:1 balun and then about another 15 feet of open ladder line to the loop. Most of the loop is around 22 feet..
Here is what is confusing me and I don't know if it's propagation or some kind of harmonic or loop elevation change etc. All bands are fine except 40 meters which is extremely noise and always seems to have a pulsing sort of noise at any time of the day. Last Tuesday I found it impossible to copy my Code Buddy from Idaho down here in Arizona on 40m. I still cannot locate and hear the 3905 Century Club net which usually operates on 7.230.5 around 0100UTC - I just get a ton of noise. I often use that net as a baseline measurement of 40m conditions. Do any of you engineering types have a thought regarding whether any antenna changes I have described could create this problem? Is there some sort of harmonic issue to look into? Are the lower freq more subject to interference from local electrical objects like transformers or street lights? Any ideas? As I say all is great except 40 meters!
Thanks for any suggestions in advance!
73/Tim NZ7C

Well, its not really the right length to operate efficiently on 40 meters...a
full wave loop on 40 would want to be approx 130ft or a little less with
insulated wire......if you go to ~260 you'd be 2 wl on 40 and a 1 wl on 80..

So, your gonna have to add or remove a bit of wire to get maximum efficiency
on 40m..good luck..

Hi Tim ,
Yes , in general , the Lower the Freq the more noise you will usually get . But it sounds to me like you have something else going on .
One more thing , If you decide to change the size of your loop , it needs to be an odd multiple of wavelengths 1 , 3 , 5 etc ... If you make it 2 WL on 40m it will be a very high impedance and hard to tune to . Merry Christmas de WH2T , Ace

Ok Ace -
Gets me closer to sorting alternatives - say, Ace, if I took a setion of wire and folded it over on itself and taped it - would that be the temporary equivalent to shortening the length? Or is the electrical length still the same?
Thanks Ace!

Thanks Steve -
I am running the whole thing the an LDG-11 tuner, but I believe I will shorten it to resonance anyway since I plan to make a separate 80 meter antenna. Although, you do always hear the maxim of "get up as much wire as you can and create the greatest circumference" ....hard to no which theiry to follow! I will have to keep in mind Ace's remark about making sure the length is an odd multiple of the operating frequencies I want to use as well.
Thanks!

Hi Tim...My loop is 2 wl on 40 and works great, the tuner in the rig tunes it
with no problem at all...although I'm sure it would be a little better if it
was an odd multiple...good luck..

Hi Tim,
If you take a section of BARE wire and fold it over on itself and
taped it - it would be the equivalent to shortening the length . If
the wire is insulated I doubt if it will work but I haven't tried it.

I also want to comment on Steve's remarks
"Hi Tim...My loop is 2 wl on 40 and works great, the tuner in the rig
tunes it with no problem at all...although I'm
sure it would be a little better if it was an odd multiple...good
luck.. Steve kb8viv "

If you decide to change the size of your loop , it
needs to be an odd multiple of wavelengths 1 , 3 , 5 etc ... If you
make it 2 WL on 40m it will be a very high impedance and harder to
tune to , not impossible to tune just harder . The automatic tuner in

my FT-920 will tune almost anything and so will my MFJ-989C . If you make a loop an odd multiple of wavelengths 1 , 3 , 5 etc ... It will resonate and you don't even need a tuner !

Hi Ace -
Monday night, my first free time, I plan to shorten the wire to a 40 m length but before doing so I will check to see if that length becomes an even multiple of the higher frequencies.
You know, another question arises. When we talk about a length being an even multiple, how close to the even multiple is significant? For example, if we say that 280' is an even multiple of 140', is 290 still close enough to an even multiple to be of significance? You don't have to asnwer becauase I plan to do some more reading now that you have helped me get into the right ballpark - but is is an interesting question.
The other "debate" I often see about loops is whether or not to include an open ladder feed line. If you plan to use it as a vertical element and the loop as a top hat, it makes sense. However many loops run the feedline right next to the house which somewhat reduces the sensibility of ther vertical element - that's when I see the comments show up about direct connection to the coax without a balun - which perhaps might be acceptable for real short runs of coax. Any thoughtson this ACE?

Hi Tim,
I use my 75 meter Full Wave Delta Loop on 75 meters much more than
any other band because 75 is my favorite band . I don't use a balun .
It will cover the entire phone band on 75 with less than a 3:1 vswr
at the band edges and flat near the middle of the band without using
a tuner ! I am feeding my loop with Coax . I am using a Quarter Wave
Matching Q Section of 75 Ohm coax coming off of the antenna to a
random length of 50 Ohm coax to reach my equipment. The formula to
figure the length of 75 ohm coax needed is " 246 VF / Freq in Mhz "
----- VF = Velocity Factor of the 75 Ohm coax used.
With my tuner it will tune 6 thu 75 meter bands . I use a 1/4 wave
inverted L antenna on 160 meter band , I don't want to mess with
shorting a feedline , I just want to flip a switch .
But if you short the feedline and feed a loop as a vertical it will
make no difference if you use coax or ladder line .

Just a thought, but don't assume the changing of the length of your loop is what caused the poor performance. You mentioned the qrn was a "pulsating" type noise and that you had been off the air for three months previously. Makes me wonder if something else is at work. For example, my daughter recently moved in with us and I couldn't figure out why my noise level on 80-meters was so high that I could barely hear the traffic net anymore. I finally tracked it down to her computer and power strip. Turn them off, the noise was gone, turn them on and hello S9 noise level. The thing is generating so much RFI that my radios in the van lock in on it from the driveway.

Ask yourself if you've added any potential RFI producers to the house in the last three months? Or did you route the antenna closer to an outside source of noise?

Food for thought, and good luck!

I am currently using the black line you buy by the pound
at commercial fishing supply stores for reparing gill nets.
It is almost invisible and seems to be holding up pretty well.
I think it is nylon or dacron line covered in tar.

Propagation has been pretty poor lately especially in high latitudes.
Christmas propagation was pretty good.

I am a firm believer in A/B tests.
Put up a dipole in addition to your loop and put the loop
and dipole on an A/B switch. You can then compare signals
between the two and then bootstrap yourself into better
and better antennas or detect when a good antenna goes bad.

Noise:

There are some good articles on the net about noise.
I learned that you can take a junk transistor portable
AM radio and go "Walk-About". This has helped me find
noise sources in my house (my sons stereo amp is bad,
my wifes dimmer lamp is much worse).

You can also hook your rig up to a car battery and
shut the power off in your house at the breaker box
then turn on breakers one at a time till you find
the circuit which has the noisy device. If there is
noise with the main breaker off then the problem is
not in your house and you can go "DF-ing" with your
transistor radio in the neighborhood.

Hello Guys,
I will be on the air all night tonight "probably' .
Mostly on 75 , But I will be happy to go to 160 meters to give a
signal report .

Not having been on this news group very long, I'm wondering if anyone has ever suggested a weekly Loop Net on say 40 or 75 or both ? Hey, perhaps one already exists ? I do like the info and the excitement of each new anticipated installation written about. There may not be much to talk about in the way of LOOPS, however it would make it easy for all who are interested to share and compare what works for them. If such a net already exists, someone point me to it. If not..... what ya say ? What would be a good time ? Week-ends I would assume ?

Well I don't claim to be familiar with all the varied nets that operate on
the bands, so I suppose we could just pick a time and place and adjust
as nessesary. We all know this here works for getting the word out. I'd
like to suggest 3930 khz and 7230 khz as a general hangout. I know my
present signal is too high to reach out past 5 land, maybe 4 land but maybe
they will be some who can make cantact with a few in their own local areas.
Twenty meters may even be good mid-day on Sunday. Oh say 14230 khz, 3pm
Sunday's and go from there ? I'd be glad to here any other suggestions.
Rather than "Call a Net", we could just ID and say something about looking
for other "Loopers" untill we see what this is going to do. Let me know
what you guys think.
Hulen
WB5UOI

P.S. I'm getting into the MMana program. That signal goes straight up on the fundamental
but starts to look real good on the second and third harmonic. :)

40 would probably be perfect if it weren't for the European broadcast
stations booming in at night, 80 gets really crowded in the evening...but 3930 or
thereabouts sounds doable, I'l listen around there tonight and see if there is a
group laying claim to that freq...although not sure if everyone can get on 80,
I know I've seen posts about 40 meter loops also...how bout this, a 80 meter
net on new years eve just to test the waters? most people will be off work..
3930 @ 8pm est?

271. Scanner Antenna people welcome.

Yahoo group: SkyWires
Date: 2004-01-01 00:17:42 UTC
From: exemptfromlife
Topic: 271 Message: 271

Anybody who is interested in Scanner Antennas is welcome to join up to the skywire loop antenna group without having to worry about the moderator (me) diddling with your email settings, or treating you like an addled lab rat whose cage has just been banged on and shaken to provoke signs of life.

For the rest of you who are wondering what I'm talking about, A certain yahoo group moderator decided (as best I can figure out) to see which of his members were still "Alive" and which ones weren't. He decided to do this by setting all members NO EMAIL option to accept email. When I came home from work yesterday my email inbox was flooded with emails from this group by people who were trying to figure out what was going on, or angry at what the moderator had done. Yahoo takes time to catch up when setting the NO EMAIL option back, so It took an hour of or so before the emails stopped, but by that time almost 50 members had decided they had had enough and pulled the plug.

The moderator was defending his action to do this after each post, by replying to each post, which was compounding both the problem and the perception that this was not a desirable action on his part. It seems the result was the group is now left with people who are die-hard members, "dead-members" who have long since abandoned their email addresses, and those who are still on holiday and haven't checked their email yet.

Once again. You can rest assure that nothing like this will ever happen on the skywires group.

Thanks.

Well Loopers I was there in 5 land at 9 est put there was this huge qso in progress. So I tuned up and down 5 khz and found WA5ZTM calling cq and I answered him on 3.935. We carried on till 9:30 when the Southwest Traffic Net started. We were both talking about antennas, loops and the Mmana program. I was hoping some of you would have heard us and jumped in. He was running the limit but I was bare "feet" :) So I didn't expect to be heard far with my signal going straight up.

I hope some of you were more successful. Please let the group know if you were. Many thanks for all of your efforts. Lets do continue to try. The 40's and 50's khz range is always busy here in 5 land. So let's continue to hang out on 3.930 unless it's better in your area elsewhere. If you get established elsewhere, please let the rest of us know about it. I'll continue to call qrz Loopers on 3.930 at night and 7.230 durring the day when I'm looking for a contact and 14.230 on weekends. (I hear more areas calls on 20M than I do on 75 or 40).

Good luck fellows !!!

278. New to Group

Yahoo group: SkyWires
Date: 2004-01-04 00:55:47 UTC
From: Dave
Topic: 278 Message: 278

Greetings to the group,
My name is Dave and I have been a ham since '94 and upgraded to Extra a couple of years ago and live in the northern part of the lower peninsular of Michigan.

I have read most of the archives and have a couples of questions;

1) I saw the mention of " NVIS type antenna", I am not familiar with that and was wondering what it is?

2) I want to get something clear in my mind, for a loop antenna, I plan on installing a 160 Meter loop, if I am understanding it correctly regardless weather a person uses coax or TV lead or ladder line, the connection is a DC short, but the radio doesn't see a short, not as far as RF is concerned.

3) I think some mentioned that the loop works well even on the new 60 Meter band as well, has any one else used it there as well and what did you think of it on that band?

From what I have read I get the idea that the loop is quieter than a dipole antenna as well as out performers a dipole too. In my situation height or the lack there of will be my problem, I suspect if I am lucky I might be able to get it up on average maybe 15 or best 20 feet off the ground, which is where my dipole antennas are now and get acceptable to me results. So I know that height off ground is one of the important things for performance but if the loop is better than a dipole it should be an improvement, the only thing that I am going to need to do is to find a source to get the 530 plus feet of wire without paying that proverbial arm and leg for it. Thanks in advance for your ideas, suggestions and commits.

John, to get the RF out of the shack, I use about 10 - 12' of RG-214, because it was handy, to a 4:1 balun, and about 40' of twin lead to a
1000' corner fed loop up at 35', I love it, probably the best antenna
I ever had, get fantastic reports, I use a manual tuner with the amp, but
the rig's internal tuner will match it on all bands, with the amp turned
off the best of both world's.
If I could be of further assistance please e-mail off the list..good luck
with your 160 meter loop, you will like it..Mac

I have read most of the archives and have a couples
of questions;

1) I saw the mention of " NVIS type antenna", I am not
familiar with that and was wondering what it is ?

=R= To some degree a SkyWire Loop Antenna is a form
of NVIS "Near Vertical Incident Skywave" Antenna.

GoTo=> http://www.qsl.net/k5eph/nvis.htm

2) I want to get something clear in my mind, for a loop
antenna, I plan on installing a 160 Meter loop, if I am
understanding it correctly regardless weather a person
uses coax or TV lead or ladder line, the connection is
a DC short, but the radio doesn't see a short, not as far
as RF is concerned.

=R= If your Loop Antenna Element is 'cut' for the 160
Meter Band. It will resonate for that band and have the
necessary RF Impedance for you to transmit and receive
properly.

3) I think some mentioned that the loop works well even on
the new 60 Meter band as well, has any one else used it
there as well and what did you think of it on that band?

=R= Good Question - I can not answer that Question.

4) From what I have read I get the idea that the loop is
quieter than a dipole antenna as well as out performers
a dipole too. In my situation height or the lack there
of will be my problem, I suspect if I am lucky I might
be able to get it up on average maybe 15 or best 20 feet
off the ground, which is where my dipole antennas are

now and get acceptable to me results. Thanks in advance for your ideas, suggestions and commits.

=R= IMHO: A Low-to-the-Ground (Near-the-Ground)
* SkyWire Loop Antenna - = V = - Dipole Antenna *

* For the same XX Meter Band; the Loop Antenna has:
* * Twice the Wire-in-the-Air as a Dipole
* * A 'greater' Signal Capture Area then the Dipole

* The LOW Horizontal "SkyWire" Loop Antenna perfroms like a NVIS type antenna and is Omni-Directional. While the LOW Dipole will exhibit some directionality.

* Think of the Loop Element as a Horizontal Folded Dipole that has the center spread out. The Folded Dipole usually performs better than a plain dipole closer to the ground.

TBL: The Loop will perform better then the Dipole.

? ? ? NOW ? IS ? THAT ? TRUE ? ? ?

282. NVIS (was: New to Group)

Yahoo group: SkyWires
Date: 2004-01-04 05:01:49 UTC
From: jimmcskate
Topic: 278 Message: 282

The term NVIS (near vertical incidence skywave) was a new one to me as well, and I have been a ham for a long time. It's sort of what happens when you have a dipole that's too low - the radiation tends towards "straight up". Straight up is not desireable for DX - for that you want a shallower take-off angle. But for closer work the NVIS behavior rocks. My loop is cut for 40m, and is not very high - 18 to 20 feet over level ground. On 40m the antenna performs really well in a radius of about 500 miles under even poor band conditions... NVIS is reliable!

On 20, 15, and 10 I am getting good DX, as the takeoff angle is lower.

Incidentally, I feed my loop with 300-ohm twinlead, and tune it through my manual Kenwood AT-200. This tuner doesn't have a balanced output, so I tune it Zepp-style: one leg goes to the tuner's random wire output, the other leg is grounded at the tuner. I can also switch in a 4:1 balun, but so far the random-wire feed has outperformed it.

This antenna design is WAY quieter than a vertical... don't have a dipole handy to compare it with, but I suspect it's not as quiet as the loop.

Have a great evening,
Jim

Thanks for the quick replies, and answers to my questions. I am now convinced that I will put `up' a 160 Meter loop over a G5RV if for no other reason than its ease of installation for me, about the only other question I have is what type of wire did you use; braided wire, household wire, also what gauge did you use and why? Was is because it was what you had laying around or was it a particular gauge because you were concerned it might stretch. I checked at a local hardware about getting a roll of wire and they only had a 500 foot spool. I am wondering if you had to have it ordered or would some place like Home Depot have longer lengths than 500 feet without asking for that arm and leg? And thanks again for your help.

Dave N8PU

>

Hi Dave, I'm sure you'll be happy with the loop, I know I am...I used 13
guage polyethylene insulated 13 strand copperclad steel wire available from
www.davisrf.com...it's expensive compared to the cheaeper store bought wire but I
have my wire in the trees and this stuff is strong and very abrasion
resistant..I only wanted to do this once hi hi...worked great..it has no memory other
than straight...I've talked to guys that hate the stuff and think it's hard to
work with..I disagree and think it was easy to work with as it comes off the
spool totally straight.

I almost went with the flexweave rope type wire but this stuff is not easy to
repair should it become necessary..it's main benefit is its flexibility, it
can even be tied into knots...but should it be necessary to make a repair
(solder) it usually breaks after a short time at the solder...

Good luck es 73's..de kb8viv/steve

Just connect the 450 ohm ladder line to the loop and
the other end to the BALUN inside the antenna tuner.
Nothing else is required!

Yes, 14.230 is the SSTV base frequency... they also use .233 and .236
when it's busy! A shift to another frequency would be appropriate.

Thank You,
Yahoo email servers must be very slow, the reason I say this is I have had to go to the groups home page and forward the messages since I joined so I would have a local copy, I even went and re-checked my preferences to make sure I had individual emails checked, I re-saved them again to make sure their computer has it the way I wanted it. SO I guess I will have to keep checking until their computers catch up with themselves. Thanks for starting this group, I am glad I found it and thanks to the others that have offered their help in answering my many questions!!

If your tuner has an internal 4:1 balun you are all set up.
If not, you might (not absolutely necessary) get a 4:1 balun
and hang it out the end of your tuner with a piece of coax.
(I assume you have enough coax to reach from your rig to the tuner.

1) NVIS
Someone else answered this.
A loop "shoots straight up" on its lowest frequency but no
worse than a dipole at the same height. This is a "good thing"
on the low bands. It has low angle gain on higher frequencies.

> 2) I want to get something clear in my mind, for a loop antenna, I plan

Sort of like a single turn coil (inductor)

> 3) I think some mentioned that the loop works well even on the new 60
> Meter band as well, has any one else used it there as well and what did
> you think of it on that band?

I use my 80 meter loop on 60 meters.
Be advized though that the rules for 60 meters are pretty restrictive.
An 80 meter loop has gain over a dipole so you need to back your power
down to just less than 25 watts on an 80 meter loop in order to not
exceed the 50 watts ERP requirement for 60 meters. (I believe
that on a 160 meter loop you would be limited to 12.5 watts)

Interestingly, inside the state of alaska the 80 meter loop did
best of my antennas. But for reaching out to Utah etc, I found that
my best lashup was to transmit on a 32 foot vertical with 97 watts
then switch to the loop to listen. (The loop has lower gain
than the loop so I can run almost 100 watts into the vert and
not exceed the 50 watt erp requirement. The vert was much
too noisy to hear the returning signals.)

298. My loop

Yahoo group: SkyWires
Date: 2004-01-05 22:57:31 UTC
From: Hal
Topic: 298 Message: 298

About a month ago I built a 40 meter loop. It's up about 35 feet at the highest point. So far I've worked the coast mostly with it on 40 meters, so NVIS isn't working on my loop. I've even worked some caribbean stations with it on 40. I run mostly QRP and get excellent reports. Just for those that are wondering its a full wave on 40 meters fed with 450 ohm ladderline to a MFJ 949E tuner. It does tune 40 thru 10, but 17 an 12 meters are a bit tricky.

Topic: 306 Message: 306

Some of you had asked about Art Bell's giant SkyWire loop. I decided
to email him and ask him about it. He responded last night. Here is
his answer.

Yes, I have a very large loop soon to be double in size (5 acres)
fed at 100 ft, the top loop is at 75 ft the 2nd loop at 68 feet.
Four foot wire mesh under the whole loop grounded to my water well.
Wire is #10.

I would like to get some more details from him if he is willing to
provide them. If you have some questions about the specifics of the
skywire, please post them here and I'll send him a consolidated
list
of questions.

I also offered for him to join the SkyWires group.

Thanks.

I have tried to catch Art on 75 meters with no success yet .
What does " fed at 100 ft " mean ? Does that mean the feed point is
100 ft above ground but most of the loop is 75 ft high ?
Is Art feeding both loops ? If so how , in phase, 90 degrees out of
phase, etc. ?
If he is not feeding the bottom loop what is it's purpose ?
Thanks , Ace www.WH2T.com

310. DX on 40m Loop

Yahoo group: SkyWires
Date: 2004-01-11 01:19:00 UTC
From: jimmcskate
Topic: 310 Message: 310

I bagged my first ever ZS this afternoon on my 40m loop! From here to the Transvaal is close to 8000 miles, and both of us were "barefoot" - which in my case is about 70 watts. I didn't expect this antenna to perform so well since it's only 18 feet above ground. (for a diagram: check out www qsl.net\wa2lgn)

In my local club (Grumman Amateur Radio Club) I am getting a reputation as a "Loop Evangelist."

73,
Smilin' Jim

311. A Loop Mystery...

Yahoo group: SkyWires
Date: 2004-01-11 13:34:30 UTC
From: jimmcskate
Topic: 311 Message: 311

Kind folks,
I have a bit of a mystery, and I'd like to call upon those skilled in transmission lines and the theory behind them.

My 40m loop is fed with 300-ohm twinlead (about 30' or so of feedline.) At the tuner end, I normally connect one leg of the twinlead to the random wire out (Kenwood AT200), and ground the other leg. I also have a 4:1 balun, but either I wound it wrong or it's the wrong "thing" to have since the antenna never performs well with it.

When I drive the line with one leg "floating" (i.e. not grounded) and the other leg connected to my tuner's Random Wire out, I get better receive performance (nearly 3 S units on my admittedly uncalibrated rig meter), and transmitting performance is either the same or better (still experimenting on air and getting signal reports.)

So: What's happening here? Any clues would be much appreciated... email me at WA2LGN<at>AOL.COM if you need more info.

Many thanks & 73,
Jim WA2LGN

What do you mean, "never performs well" ? Do you mean your tuner won't bring the SWR down to an acceptable level when you feed the 300 ohm line with the balun?

Well Jim, when you connect one wire to the 'Random Wire' out on your tuner you convert your arrangement to a "Random Wire" antenna! Trying to explain performance of this arrangement is the same as trying to explain performance when you connect you tuner to your rain gutter. In short, you don't have a loop but some kind of strange random wire antenna. If it works use it.

Topic: 311 Message: 313

Using the balun and the tuner, I can get the SWR down without trouble - but the signal reports are markedly worse. It's very fast to switch configurations, so I can try it several ways in a single QSO.

Note that I'm not using the "vertical/top hat" configuration, i.e. I am not shorting the feedline at the transmitter and driving the thing as an inverted "L". This configuration doesn't perform as well as leaving one feedline leg floating.

It works and I love it and I will continue to experiment... but it's still a mystery to me ;-)

Thanks for your help!
Jim

Here is Art's response to the questions posed..

Yes feed at 100 ft. BOTH loops fed at same point and quickly angle away from each other. VERY BROAD 3.5-4MHZ no re-tuning. They are IN PHASE. Gain is added. (Don't ask me how) Diversity? Idea from book about W6AM who did the same thing to his Rhombic's and found a second wire below the main added a lot of gain and made them VERY broad. I use a commercial piece of gear which keeps the loops at dc ground at all times+ lightning protection.

thanks.

Wonder if Art Bell would be the guest of the 'hour' on one of the Echolink Conference Servers where he could talk on the topic of Large Loops (his) and how it is configured and how it works?

I bet we could get server time from one of the conferences on Echolink.

and then he could take some questions (canned if necessary) and respond directly.

Let me know if Art is open to possibly doing this and I'll contact a Server Owner.

Might be a lossy balun.. If you had two of them, you could put them
back to back into a dummy load and measure the power into the
pair and the power out of the pair and see if there was a lot of loss.
If you wired it yourself, double check. Did you use a toroid sized
for your power level?

> When I drive the line with one leg "floating" (i.e. not grounded)

Are you seeing the s-meter reading of noise?
I would expect that disconnecting one leg of the loop
would raise your noise level up a bunch... Check the
meter reading on a SW broadcast carrier and note the
difference there. If it still shows a high s-meter reading
on signals (not noise) then it could be that releasing
one leg of the feedline changes the shape of the radiation
pattern enough to cause the difference.

Try borrowing a tuner with a balun from a ham friend
and see how that tuner acts with your setup.

JMS,

The 300 Ohm Twin Lead should work well with your Tuner
connected as a Balanced Antenna; without the Matching
Transformer.

If your 4:1 Matching Transformer is wire up in to the
feedline circuit as a Balun (BAL > UN) then it should work.

IMHO: Your best use of the 4:1 BALUN is at the Antenna
Element and FeedLine Junction. Using a Coax Cable FeedLine
between the Antenna Element and the Tuner/Receiver.

Hey, What Works... W O R K S !
(Be Happy : Just Use It !)

Hello Everyone,

I just got done reading through the past messages.
A lot of good information!

My antenna sounds odd enough to fit right in!
Even with my restrictions (Aptment dweller in stelth mode)
I was very lucky. Behind the apartment building complex is
a unkept greenway and a creek.

I was able to get 368 feet
of insulated #12 copper stranded wire. It floats in the
trees with only the feed point secured. The AVERAGE height
is 45 feet, with the highest point being 60 feet and the
lowest point being at 35 foot. It's not a perfect square
and I'm using a 1:1 balun with part of the RG-8 6 inches
underground.

Radios used are: IC-745
FT-707

I can contact almost every one I can hear.

Have you put a meter across the feedline? It should
read the resistance of the wire length which for a 40
meter loop wont be much, only a few ohms. If it reads
open then you have a broken wire in the feedline or
antenna somewhere. If it reads high resistance say 20
ohms or more you have a poor connection somewhere.
When you first put up a loop you should always check
the resistance and post it at the antenna connection
in the shack and check it every week or so or if you
have a big jump in the inductor/capacitor settings
when tuning up on a frequency you use all the time
like a net or where you meet your friends to talk.
This way you will know when you develop a problem with
your antenna.

322. Loop Question

Yahoo group: SkyWires
Date: 2004-01-14 03:16:45 UTC
From: Dave
Topic: 322 Message: 322

Just put up, not very high about 10 feet off ground, it is a 160 meter loop, I/we (my son and I) will go back out and do some better measuring of the length to see what we got exactly. We were racing against dark; the one thing I noticed first off on some bands it is a very broad band tune (easy), but on some it is VERY critical to not hardly breath when I am adjusting the tuner, MFJ VERSA TUNER II, model 944. I am direct connecting the loop with about 20 feet of RG58U coax. The only band that doesn't want to tune in is 40 Meter, only the top 50 KC or there abouts tunes acceptable to me. Now I am guessing and hoping that this isn't normal. Am I correct in that assumption. I know that getting it up higher would help out a lot, but that really isn't an option right now. Any other ideas to try would be appreciated.

Thanks and 73

Dave,
Try tuning this on 40 using the vertical/top hat configuration - short the coax at the transmitter and drive it as a random wire against ground. You could make up a special connector for this out of a short length of RG-8 coax - should be pretty straightforward.

73,
Jim

Dave I found with my large loop that the groune from my tuner was very
very important, I run heavy wire from a ground rod direct to the tuner,
it helped tuning and also noise a bunch

Topic: 322 Message: 328

..,or try some twinlead or window wire or ladderline

I have read that since open wire line has a higher
characteristic impedance, it is easier to tuneup
than 50 ohm coax. I dont believe I have noticed
that behavior but you can try it and see how that
works for you.

I have read that 55 feet is a good non-resonant length for
openwire feeder but experiment and see what works.

I have seen that feedline lengths have a huge impact
on tunablilty of antennas. I borrowed an mfj antenna
analyzer for an afternoon and attached to my loop and noticed
that i could change the length of my loop by 20 feet or more
and I still had a nice dip in swr on the 17 meter band
no matter what the length of the antenna.
I was actually trying to make the 80 meter antenna resonante
on 20 meters. It took me a bit to realize that the feedline was
causing the behavior.

I am having trouble tuning on 160 even though that is what I made the loop for, it tunes real good every where else. I am using 70' of 450ohm ladder line straight to my MFJ 989c tunner. Any one got any ideas what to try next?

I am having trouble tuning on 160 even though that is what I made the loop for, it tunes real good every where else. I am using 70' of 450ohm ladder line straight to my MFJ 989c tunner. Any one got any ideas what to try next?

KC,

If your Skywire Loop Antenna is 'cut' for 160 Meters:

1. Check your connections.

2. Try using it on 160 Meters without the MFJ-989
Tuner. [" Low Power ONLY for Testing "]

3. Try changing the Feed Line Length from 70 Feet to:
* Shorten to 66 Feet - If Possible.
* Lengthen to 75 Feet or 87.5 feet - If Practical.

4. Type using a 1:1 Matching Transformer between the
Antenna Element and the FeedLine. (Outside Up-in-the-Air)

Well it is trying to tick me off now, If I feed it as a vertical it
tunes very easy on 160, 75, and 40, but dont hear as good and dont tune
on the higher bands very good at all which it did the other way.

333. Re: Loop Question = Check & Re-Check

Yahoo group: SkyWires
Date: 2004-01-16 19:12:07 UTC
From: R H F
Topic: 322 Message: 333

KC,

I guess my first assumption is that your stated the you
made this SkyWire Loop Antenna for the 160 Meter Band.

The the Antenna Loop Element should be about 525 Feet long.
? Is that Correct ? - ? If Not Then - What Length Is It ?

What type of wire did you use for the Antenna Element ?
? Is the Wire Continuos (One Piece) -or- Joined Pieces ?
? I There are Joints - What Type ?
[Should be Western Union both Soldered and Wrapped]

How is the Antenna Element Rigged ? -&- Insulated ?
? Any Bare Wire on any Tree Limbs ?
[Minimum Clearence of Three Feet at All Points]

Did you 'check' the Continuity of the Antenna Loop Element ?

Usually smaller/shorter loops that are designed for 80M
or 40M are used as Vertical Top on 160M with some success.

It is easy to Load-Up a piece of wire with an antenna tuner,
but that in and of itself does not mean that your are getting
out or that you can Hear in return.

I will repeat myself. If your have a a 160 Meter Band
SkyWire Loop Antenna cut at about 525 Feet: Then an
Antenna Tuner should not be required at low power for
testing and evaluation; until you have resolved your
problems.
1. Check & Re-Check the Antenna Loop Element
2. Check & Re-Check the FeedLine
3. Try 'different' Lenghts of 450 Ohm Ladder Line
FeedLine for the Best performance on the 160 Meter Band.
4. Then use the Antenna Tuner for the rest of the bands.

If insulated wire is used a 3 to 5% shortening will be required to obtain resonance . This is due to insulated wires lower velocity factor usually .97 to .95 .

KC,

YES - An "Insulated Wire" usually is TRIMMED to a Length
that is Less Than the Formula/Calculated Wave Length (WL)
for a Bare Wire.

BUT - Remember these Calculations for a Wave Length,
Half WL and Quarter WL Resonant Antenna Element are for
the Optimum Antenna Mounting Height.

TRIMMED - This is Why I Say TRIMMED. Since most 160M
SkyWave Loop Antennas are Not Set at 1/4WL = 132Ft;
1/8WL=66Ft; 1/16WL=33Ft.

NOTE: Practical Resonance = Getting Out and Being Heard
+ Hearing the other Guy + and Having a Low SWR. Is a
Combination of FACTORS when a Relatively Large Antenna
Element is Mounted "So-Close-To" the Ground.

THE PROCESS: So my recommendation is to have the Antenna
'connected' using your FeedLine directly to the transmitter
(without an Antenna Tuner) using low power for SWR Testing.

Start at the Full Length of the Bare Wire Calculated
Length and TRIM One Percent (1%) Ruffly Five Feet and
Three Inches (5' 3") at a Time.

First Test; Then Trim and Test Again; until you reach your
Optimum Trimmed Antenna Point for best operating conditions.

How do you hook up 450ohm ladder line directly to a Radio?

All modern HF transceivers have an unbalanced input with a coaxial connector for 50 ohm coaxial cable. The usual method of connecting to a balanced feed line is to use a 4:1 balanced to unbalanced device called a 'balun'. Now, unless you have a good match as is, you will in all likely hood connect the unbalanced output of the 'balun' to the coax input of the transceiver with an antenna tuner. The majority of modern antenna tuners match unbalanced to unbalanced lines. In addition most modern antenna tuners incorporate a 4:1 'balun' for the express purpose of matching balanced lines such as the 450 ohm ladder line or 300 ohm TV twinlead.

If you are connecting to a receiver instead of a transceiver you will note that some have provision for connecting a balanced line directly to the radio. In this case what you will see at the back of the radio is both a coax connector and a pair of screw terminal connectors for connecting balanced lines directly. Such receivers have a built in 'balun' and for receive purposes they don't try to actually tune the antenna.

Along the same lines as the question below.

Do you really bring the ladderline into the house? I guess lightening protection is necessary too but for instance in my home. the radio is adjacent to an outside wall (approx) 4 ft from the actual wall, so I bring the ladderline in (thru the floor) and directly to the tuner/radio? Should I use a coaxial cable as a shielded feed in case the path is near a metal stud or other metallic object?

Hmmm

450 ohm ladder line can represent a mechanical problem bringing it to the operating position. There are a couple of ways of handling it:

- bring the ladder line in as close as convenient and connect to a 4:1 balun. Then you can run coax cable from the coax side of your balun to your xcvr or antenna tuner as the case may be. This requires either removing the balun from your tuner and relocating it or buying a separate balun. If your tuner already includes a balun I can see you not wanting the extra work and or expense.

- another way of handling it is to end your 450 ohm ladder line at a convenient location and connecting a good quality 300 ohm TV twin-lead to it. You then run the TV twin-lead to the balanced input on your antenna tuner as it is as convenient as coax cable. TV twin-lead works very well and will have no problem handling RF power in the 100W range. TV twin-lead has a bit more loss than 450 ladder-line but nothing to worry about with a short run.

I ran a 100' inverted vee antenna up 30' above the peak of a second story roof. I connected the center of the inverted vee with 300 ohm TV feed-line down to the rig in the basement (a good 60') to an antenna tuner. I used to run a full 100W input and full AM. It was a great antenna and never had a bit of problem. In fact you can get all kinds of insulated stand-off hardware at your local RadioShack or similar store.

PS I've never had lightning problem. However if your concerned you can locate a DPDT knife switch at a convenient location ..... throw the switch one way to connect the antenna to your rig and other way to connect the antenna to a convenient ground eg a water pipe.

I run the 450ohm ladderline to the tuner in the house, It seemes the
best way to me, why change, If I used coaxial cable I would run it uo
to the loop also. Keith

Zip cord wire is also fine to use on the 4 to 1 BALUN and half the trouble to wind up on the pvc pipe! Also the large ferite rod used in old AM radios works very well. Just remove all the old wire, wrap with black electrical tape and wind up with ZIP cord wire. Wrap again with another layer of black electrical tape. Do not try to use the very small rod used in modern radios as there too small to work properly unless you use very small wire and run QRP only.

345. Lets Talk Batteries and Grounds

Yahoo group: SkyWires
Date: 2004-01-19 03:39:02 UTC
From: Burr Patterson, Jr.
Topic: 345 Message: 345

This is the way I do it and I like it.

I run all my short-wave and scanners of 12v car batteries:
I have a cheap 12v battery charger from PIP Boys ($29) to recharge the batteries after I turn off the radios. I DO NOT charge them while I am using the radios because I want to keep the AC hum away from my radios.
I use wet batteries with caps so I can add water as needed, I set them on a piece of wood for the garage battery and have a plastic box for the house battery. If your wife doesn't like the battery in the house run the wife off.

Grounding antennas and mast:
I use a telephone grounding block on the antenna leads at the first place it touches the house grounded to a ground rod, all of this is at the bass of the mast. I put the bottom of the mast about 6 inches in the ground beside the ground rod. Because I live in the dessert I have 24 rose bushes on a drip watering system so I just added a drip at the ground rod and it and the mast get 20 minutes of drips twice a day. I also ground the sheath on the coax cable I use to feed into the house and garage and keep ALL THE ABOVE AWAY FROM ANY AC WIRES OR LIGHTS.

Use the grounds, no playing or you will burn your house down at sometime. NOTHING WILL STOP A DIRECT LIGHTNING STRIKE BUT THE STATIC FROM A CLOSE (one mile) WILL BURN UP YOU RADIOS.
Be sure to get lots of "carbons" when you get the grounding blocks (Graybar has them) and replace them after a lighting storm.

My time on the soap box about grounding this year. I'm going to the gym, Cya

346. Balanced Feedlines and Baluns

Yahoo group: SkyWires
Date: 2004-01-21 07:03:14 UTC
From: science_math
Topic: 346 Message: 346

Hello Loopers from Mike. Thanks for taking the time to share things you know and have learned about loop antennas. I have access to 60 acres of land [30 wooded] which is "begging" for a wonderful variety of wire antennas. With respect to loops and other antennas in general that are fed with balanced line, should I be concerned with RF in the shack, and if it is an issue, can an appropriate balun be placed anywhere in between the antenna and the tuner? For example, can an appropriate balun be placed right at the feed point of a loop and coax run from that point to the shack? Or must the balanced feedline be a given length, or as long as possible and the balun placed close to the tuner? My guess would be that if the run of coax is long, the cost/loss aspect of coax would make a balanced feeder more attractive, but that's only my guess.

And with respect to purchasing commercial baluns, are there, in your opinion, some baluns that are better constructed than others?

Thanks. During the upcoming warmer months, I plan to be stringing a great deal of wire and I will share with the group different things I learn.

Well, first off, it's a bit long/or short, for 60 meters, depending how you
look at it; it's way longer than a full wave but less than 2 wavelengths
(1005/freq.) For receive, it should work ok, a tuner would help a bit...also, if
you use metal poles, make sure you isolate them from the wire as they may couple
with it and become part of the antenna..this may be good or bad...as far as
guage wire, the larger the wire the better, specially for long stretches...I
used 13guage copper clad steal pe insulated wire and its working very well for
long stretches..good luck..

>With respect to loops and other antennas in general
>that are fed with balanced line, should I be concerned with RF in the
>shack, and if it is an issue,

Generally, no. Unlike a random wire, a balanced feed line is not a radiating part of the antenna. If you have a balanced antenna eg a loop or a dipole and you are feeding with a balanced feed line, the feed line will not be a strong radiator of RF. Just because a balanced feed line is open wire and not shielded does not mean it will radiate RF. The theory is that as long as the antenna and the feed line are balanced the antenna currents at any particular point along the line will be in balance and cancel each other out. This does not mean there will not be standing waves along the feed line . However the reason open wire balanced feed line is popular is that energy loss due to standing waves is quite low as compared to coaxial feed line.

>can an appropriate balun be placed
>anywhere in between the antenna and the tuner? For example, can an
>appropriate balun be placed right at the feed point of a loop and
>coax run from that point to the shack?

As mentioned above, the usual reason for using a balanced feed line is to limit feed line loss in situations where there is a high Standing Wave Ratio (SWR) between the antenna and the output of the transmitter. So, for example. You have an antenna with a balanced feed point located approximately 100 ft away from you transceiver which has an unbalanced output fixed at 50 ohms. You would like to use this antenna on 3 different bands and you estimate that depending on the frequency the impedance of the antenna could be anywhere between 75 and 600 ohms. Also, your transceiver is QRP (eg puts out 5 watts or less) and you want to keep loss to minimum. What strategy should I use?

- I need to convert balanced to unbalanced
..... .get a balun!
- I need to minimize power
loss ..... get some
open wire feed line.
- I need to match a range of antenna impedances to my transceiver
..... get an antenna tuner

Therefor the ideal strategy will be - make the open wire feed line as long as possible .... right up to the antenna tuner if possible and limit the coaxial cable run from the output of the tuner to the transceiver. In this case the balun will be built into the tuner (most tuners include a built in balun for balanced lines). If for some reason you cannot bring the

balanced line to the operating position then locate an external balun at a location as close to the operating position as possible and connect the ouput of the balun to the antenna tuner with the highest quality, lowest loss coax you can afford.

> Or must the balanced feedline
>be a given length, or as long as possible and the balun placed close
>to the tuner? My guess would be that if the run of coax is long, the
>cost/loss aspect of coax would make a balanced feeder more
>attractive, but that's only my guess.

There are special cases where the design incorporates balanced feed line as part of the antenna in which case the length of the feedline is specific. Another situation is that the antenna is designed for a specific frequency and a special 1:1 balun is located right at the feedpoint of the antenna and the whole length of the feedline is coaxial cable .... eg dipoles and yagi antennas.

>And with respect to purchasing commercial baluns, are there, in your
>opinion, some baluns that are better constructed than others?
Baluns are quite easy to construct. Baluns that are included in antenna tuners are simply composed of a ferrite core and a few feet of wire and nothing more. However if you are going to locate the balun outside the tuner and even outside the house then the balun design must include provisions for securing it, shielding it from weather, and connectors to the coax and the balanced feed point. 90% of the cost of these baluns is a result of these necessities.

>Thanks. During the upcoming warmer months, I plan to be stringing a
>great deal of wire and I will share with the group different things I
>learn.
>

I also have a forested area and have spent many a happy hour stringing up wire antennas .... have fun this summer.

#2 ..... Hi. I ground all my antennas with relays. My long wire comes down to a large open relay while all my other antennas use coax relays .... it takes power to un-ground an antenna and connect it to the feed line to the operating position. If there are no lights on my switching panel then everything is grounded. All the relays are located at the entry point to the house .... next to the ground wire at the basement window. I have never had a problem with static discharge at this location. However, when I was in Saskatchewan I found that real dry windy days could build up tremendous static voltages. I had a 200' long wire that could throw a spark 4 to 6 inches. I used tube type equipment then and don't remember it ever causing damage. I have always used a 'link' type of antenna tuner which keeps feed lines at DC ground potential.

Jeff -
I have operated with a loop on my roof for three years. It is roughly 200 feet in length and ranges in height from 20 to 30 feet. It is fed with ladder line which is connected to a 4:1 balun which is then connected to about 20 feet of coax to get into my shack. I am able to work 80 meters and up all over the world. It is a great antenna and vastly underated. I don't get to operate as much as sum, but I know that I will be able to finish my 5 band WAS ca award with it as well as DXCC. Hope that helps. PS Loops can throw some RFI so you may have to put filters on your phone etc.

I have heard stories that NewZealand hams like to wrap their
houses in a loop of wire. Sort of an invisible skywire.

I would think that if you dont have a metal roof this should work
pretty well. Insulating the wire from the house would be important.

I have looked all over the net and cant find a writeup on
this "New Zeland Loop" other than an ARRL comment about the
loop and how popular it is in ZL. It would be cool if someone
could do some A/B tests and tell us about how it performs vs
a dipole at the same height.

Jeff,

So far with my loop I have had the best luck wit just a center connector and a coax choke.

I'tried a 4:1 balun, 3:1, and 1:1 balun (current type)for my setup the 3:1 cam in second, the 1:1 last. For me ANY balun made my tuner very touchy to tune. The 3:1 was not bad to tune. But, the other two came down fast. Hated them.

This is a perfect application for Mmana modeling software - it's a shareware on the web, and I learned of it from this list. I am a novice at this program (its user interface is a bit rough) but I put in the numbers you described. Provided that I entered the stuff correctly, your antenna pattern is very slightly lopsided on the lower frequencies, with lobes
between the low corner and the diagonal across from it. The angle of incidence is also higher in the direction of the low corner, on the lower (40/80/160m) bands.

Just to check my work, I'd love it if other people dug into this question to see if I used the darned software correctly!

Have a great day,
Jim

DM2K,

This is where Antenna Modeling Software would be of Great Help.

My 'guess' is that for better low frequency operations
having more separation between the Two Loop Antenna
Elements in your SkyWire Loop Antenna would be better.
[Vertically 'Stacked' Two Loop - SkyWire Loop Antenna]

If the Top Loop Antenna Element is set at 20 Feet; then
the Bottom Loop Antenna Element would be at 10Ft to 15Ft.

For a Receive ONLY SkyWAve Antenna your 300 Foot [Square]
Size with Two Loop Antenna Elements would not be a problem.

However, for a SkyWire Loop Antenna used for Transmiting
then 'adjusting' your Loop Antenna Element Size "Down"
to 268 Feet with Four(4) 67 Feet Sides to your Square
for the 80 Meter Band would most likely work better for
the Amateur / HAM Bands.

AGAIN - Maybe someone with Antenna Modeling Software
would run the program and offer some Help.

DM2K,

One Single Continous Piece of Wire:
Starting at the Top and looping around for One Turn and
transitioning down to the Lower Loop that loops around
back to the Starting point and transitioning back up to
the Feed Point. Try to keep these two transitioning
up & down wires separated by a foot or two.

Generally speaking, you find loading coils used to tune unbalanced antennas, (mostly verticals) to allow for a shorter element to be resonant at a given wavelength. With loops, you want to tune a lower frequency, you make a bigger diameter, (sometimes cumbersome) or add more turns. Balanced loading coils might work, but with loops, aperture and number of turns is everything.

John,

Correct me if I am misunderstand you.

Are you saying that a skyloop style antenna acts like a Multi-Turn Receiving Loop? I am using a 40m 1.25 wave skywave, and was looking for a way to get more wire in the air to make it a better DX antenna on 80m. After I posted that question I realized that it would only help the "tuner" tune easier on 80m. But, only doing some "brain storming" with out deep thought. (hi hi) Do you have any ideas on a Multi-Turn SkyLoop? Feeding, Supporting? Spacing Ect. ?

Michael, Are you employing it as an open or closed loop? You won't benefit much more if it's open. After doing some basic research in books and in groups, I just do trial and error experimentation. Joe Carr's Receiving Antenna Handbook is my main reference. Chapter 8 has some info on large loops. I imagine his book dedicated to loops does too but i don't have it handy. Check it out. You'll get a lot more accurate info than i can give you!

>
>square 300 ft 20 ft up

This is an intriguing question and the simple answer is yes, it will work. However, the bottom line is that it is probably a lot of work for what seems to be slightly poorer performance than a normal 1-turn loop.

I modeled the following with EZNEC 3.0:
"1T" = 75x75 square loop, 20 feet high, #14 wire, fed near one corner.

"2T" = 75x75 loops, first turn 20 feet high, second turn 19 feet high, #14, fed on top wire near corner, with a transposed 1 foot section of 450 ohm ladder line at the opposite corner connecting the top and bottom wires (which puts them in series).

"2C" = 75x75 loops, 20 feet & 19 feet, #14, fed on top wire near corner, with a 1 foot section of 450 ohm line (no transposition) in parallel with the feedpoint and connected to the bottom wire (places the two turns in parallel, effectively increasing the conductor diameter).

I compared the gain at 1 MHz, 3.34 MHz, and 6 MHz. I also swept the impedances from 0.5 to 30 MHz in 0.5 MHz steps to see what sort of variation occurs to check for the effectiveness of wideband compromise matching for receiving.

Here is a summary of the results:
All three loops have their first resonance at 3.34 MHz +/- 0.01 MHz. As you might expect, the 2 turn loop has an impedance very nearly 4 times that of the 1 turn or 2 conductor parallel loops (analogous to a folded dipole). (1T = 84 ohms, 2T = 331 ohms, 2C = 83 ohms) The gain at 30 degrees above the horizon peaks at -3.2 dBi within 0.1 dB for all three. At the zenith, for toasting clouds, the gain is +3.7 dBi for all.

The "gains" for 30 degree elevation, at 1 MHz are similar:
1T= -23.1 dBi, 2T= -24.6 dBi, 2C= -22.7 dBi.

At 6 MHz, all have a nearly identical egg-shaped pattern at a 30 degree elevation:
1T= +0.3 dBi, 2T= -0.3 dBi, 2C= +0.2 dBi.

The biggest differences are in the variation of the antenna impedance over the 0.5 to 30 MHz range. Taking a cue from our old friend John Doty from 1996 Dec 23, as noted

at http://www.anarc.org/naswa/badx/antennas/SWL_longwire.html , I was curious whether a 450 ohm or other matching transformer would reduce the mismatch loss from the antenna over the frequency range for the loops. It turns out that this is quite practical with the 1T and 2C loops, but the 2T loop isn't quite as good, since the range of feedpoint impedances is much greater. Here is a general idea of the variations of the resistive components of the impedances:
1T = 66 to 4821 ohms (73:1)
2T = 13 to 7254 ohms (571:1) !!
2C = 58 to 2272 ohms (39:1)

For SWL receiving, with the 1T loop, the best compromise match occurs with an 800 ohm transformer (4:1 turns ratio with a 50 ohm load). For the 2T and 2C loops, a 450 ohm transformer (3:1 turns ratio) looks best. However, due to the larger impedance swings with the 2T loop, the mismatch losses vary almost 10 dB peak-to-peak between 4 MHz and 30 MHz, compared to a variation of only about 5 dB p-p for the 1T and 2C loops. The 2T loop is OK, but the 1T and 2C are better.

For ham transmitting, both the 2T and 2C have wider SWR bandwidths around the first resonance than the 1T, but the lower impedance of the 2C loop is probably easier to match. It also produces lower voltages when your 4-1000 is on line. 8-)

Heres my story.

I used to live about 2 miles from one of the southern hemispheres
largest radio stations.
It is located in the suburb Hamersley in Perth , Western Australia.
The WRTH books had it written up as being in Waneroo ,,which is
aktualy another 18 or so miles north of where it realy is.
This radio station had 3 MW transmitters going 24 hours a day
omnidirectionaly ,,each at 50Kw if i remember corectly and a whole
bunch of beamed SW regional ABC radio stations.(6wf,6wn,vlw)

Western Oz is a huge place and when this site was set up (1950ś??) it
must have been cheaper to beam hf transmisions to the outback than
have local repeaters of some sort., where talking 1000ś of miles here.=

When you add up all the watts output from this place its verry
impressive ,,ime just glad i wasnt getting their electricity bill.

Now my house happened to be directly in the path of a HF beam , i
could easily see their curtain antenna from my back yard.
This is DISASTEROUS for the SWL , HAM or CBér.
I loved my shortwaves , so when i set it up with some sort of long
wire antenna it was stone deaf.
HUH????

There is so much rf floating around that it throttles back the radios
agc to nothing.
So ,ok ,,use a smaller antenna ,,well , it gets better , but then you
run out of usable signal strength.
So i tried all sorts of high pass filters to cut hard everything below
12MHZ ,and even tho i sacrificed everthing below that ..It was
somewhat a semi-success above that.
The SW broadcasts from up the road where in the 31Mb and below.

I even tried much newer and much more expensive radios in an endevour
to get ,,,sumthing.
Forget about portables ..!! rubbish.

As time went on ,,computers and fluro lights came more popular and
living across the road from a shopping centre with all there
electronic noise makers it was just getting hopeless.
Even piking up the BBC or VOA was near on impossible.

Then i found on the net info on full wave loops.
They said that it was low in gain ,,but verry low in man made noise.
I liked the sound of that.

What i ended up with after sum experimenting was a full wave loop
,,tuned to aproximately 10Mhz.
I had it aranged as a horizonatl square with each leg 7 meters long.
The wire was just solid hookup wire that i had spare from an irigation
job i did.
It was plastic coated ,,in green ,,which when just laying on my tiled
roof , which was also green ,,was invisible.
I used a balun off a tv antenna , 4 to 1 to the coax.
Yes i DID know that as that balun was desighn for VHF that there would
be losses when used at HF., but i didnt care.
The coax which was just long enuff ran into my shack into the back of
my YAESU FRG-7000.

And you know what ..it works !!!

For how much wire i had up there signal strength would be higher with
a longwire but i had dropped from a noise level of 10+ down to 2.
An equivealent length longwire for example mite have given me a signal
of a 9 maybe ,,but with the loop it was down to a 7 ,,,but still
,.,.,.a 7 with a noise floor of 2 is a way lot better than 10+ of noise.

I hope your following wat ime saying here.

Another thing i found was that the FRG-7000 and another radio DX-302
worked noticeably better than newer ¨high tech¨ radios.
These share the Barlow Wadley circuitry which has tunable front ends
from the front panel.

Enyway ,,so thats my story ..now days i am out in the country on a
farm where i can try out long wires hundreds of feet long if i wish
and a noise level ,,well , internal circuitry noise is my only trublez
now :-)

Hope u like my story:-)

gregW:-)

Loved it Greg.
You've certainly earned your quiet time in the country!!
I live in a fairly electrically noisy environment, (North London, UK) but
your huge transmitters take the prize for front-end testing.

I used to have an FRG7700 and found that connected to a 160ft long wire, it
also overloaded to S9+10 on the meter, due to two powerful local AM
frequencies, (BBC Radio 1 and Capital radio, now called Capital gold).

For a quick solution I made two wave traps and, with the S-Meter, tuned them
for maximum dip, (min signal) on the two respective frequencies. These traps
worked a treat and successfully stopped the overload.
The traps were made from two MW coins from an old push button car radio,
connected in parallel with, I think 100pf variable capacitors. They were inserted
in line with the antenna feed and tuned by moving the ferrite slug in the
coil centre and then adjusting the variable capacitor.
An ATU was also used to better match the wire.
Later on I did a swap and gave the 7700 away in exchange for an excellent
condition RACAL RA17L, (Superb). which I used for about ten years in combination
with an Heathkit DX40 transmitter for my morse only amateur station.
Still got my licence but don't have a transmitting station just now.
I spend some spare time playing with my newly aquired Yupiteru MVT 7100.
I think I've become a scanner nut!!
All the best.

Hi Jeff:

I'm curious how you place the loop wire on the roof of your house. Do you use standoffs of some kind or other, or do you simply lay the wire on the shingles. If so, do you use any kind of clips to hold the wire down to the shingles? It is a very interesting idea. I operate almost exclusively on 20 mtr and hve a very nice monoband beam up for that purpose. However I am also interested in 80 and 40 mtrs. I really like the loop idea since it avoids a lot of digging in the yard putting in radials.

I'm interested how you handled the mechanical aspect of putting up your roof loop hi.

Michael:

For what it's worth here is a simple way of creating a 2 turn loop: use (zip cord), you know, the simple lamp cord. I built a 2 turn loop for 20M portable work using this method and it works like a charm. I wanted a 'Delta' antenna that I could quickly hang up between 2 trees with the feed point close to the ground. However a full wavelength is about 64' making it a bit bulky for quick assembly out in the woods.

So I picked up some lamp cord .... #18 wire which is nice an flexible. I cut the wire to 1/2 wavelength, about 32'. I then soldered one wire to the other wire at the other end forming a 2 turn loop with a total length of 64'. Now when I hang it up as a Delta antenna each side of the triangle is a little over 10', much easier to handle in portable situations. I use the same lamp cord as the feed line (10-15') to my antenna tuner. It easily tunes to 1:1 and performance seems to comparable to full size dipole. It is also handy that it is available at your local hardware store.

Now I have been thinking of a roof top loop at home for 80M & 40M. Full size on 80M would be approx. 260' ..... while a 2 turn loop using zip cord would shorten that to about 130' which is more convenient for my modest bungalow roof. If it worked for my portable loop I don't see why it shouldn't work for a roof loop. I'll have to try it in the spring .... when all the snow is gone hi. I have been giving thought as to how to mechanically mount this on the roof. Again I will have to check out the handy hardware store. There must be some kind of clips to hold wire to roof shingles. I know I have seen heating cables fastened to the roof. Home Hardware should have an answer hi.

Greg W., onegammyleg@..., says,
"... 2 miles from ...3 MW transmitters going 24 hours a day...
...full wave loop tuned to aproximately 10Mhz. ..."

Wow!
Maybe you could have built a loop or two
tuned to the SW station's main frequencies
and used a RF-DC-AC inverter system
to provide electrical power for your whole house.
With 24 hour operation,
you wouldn't even need battery backup.

Great story.
Thanks for posting it.

Cheers, 73,

Ron McConnell

Check out:
http://www.qsl.net/mmhamsoft/mmana/

On that page you will see nec-2 for mmana

I used it to convert between mmana and nec-2

I might still have the files at home somewhere
If I find them I will post them. I am not that
familiar with NEC-2 so I may have not done it
properly.

I'd make it 2 wavelengths in circumference for the best gain. See
http://www.cebik.com/atl1.html for patterns and info on where to feed it, etc.

Hi Roger ,
I would put up a Full Wave Loop. 99 feet of wire in a square with 24 feet 9 inches on each side .
I would NOT make the loop 2 wavelengths. If you make it 2 wavelengths it will have a high VSWR at 10.15 Mhz
Here is a chart showing the SWR to Frequency relationship of an antenna that is resonant at 5 Mhz

If you feed the Full wave Loop antenna direct with a single piece of coax you can only adjust add/prune the antenna till the VSWR gets down to about 1.7:1 at resonance , so you will probably want to use a tuner if you want to cover an entire HF band . And Yes the tuner in the radio will work fine as long as you are not using a linear amplifier. The impedance of a Full Wave Loop antenna is theoretically in the vicinity of 100 ohms. That is why I use a 75 ohm "Q section" to provide a perfect match to the 50 ohm coax. My Loop antenna is flat 1:1 VSWR around 3.875 Mhz and rises to about 2:1 SWR at 3.75 and 4 Mhz . So I cover the entire 75 meter band without using a tuner.

Here is How I Do It.

Connect the shield of a "Short Piece" of 75 ohm coax to one end of the loop antenna , Connect the center of the 75 ohm coax to the other end of the loop antenna. The length of the 75 ohm coax is most important. It will be used as a Q section.
To determine the length to use, Use this formula "Length in feet = 246 x VF / Freq in Mhz" VF = the Velocity Factor of the coax. So multiply 246 by the Velocity Factor of the coax , Then divide by the frequency .

If you use RG59 or RG11 with a Velocity Factor of 0.66 , For the 75 meter band the Piece of 75 ohm coax should be about 42 feet long , It doesn't need to be exact . RG59 and RG11 coax usually have a Velocity Factor of 0.66 , Foam dielectric coax such as RG6 might have a Velocity Factor of 0.81 or more.

Put a PL259 coax connector on the unused end of the 75 ohm coax, Screw a PL258 double female coax connector onto this PL259 coax connector. Then connect 50 ohm coax to the other side of the PL258 double female coax connector, Use any length 50 ohm coax needed to reach your Transceiver.

CORRECTION : The chart shows the Mismatch Loss to Frequency
relationship of an antenna that is resonant at 5 Mhz.
But the VSWR will also act in a similar manner as the Mismatch Loss
by rising or falling in direct proportion with it.

Actually this chart is for a 15m vertical antenna (it is from John Doty's correspondence on longwire matching at http://www.anarc.org/naswa/badx/antennas/SWL_longwire.html).

The impedance of a 1 wavelength loop is about 117 ohms (#14 wire, mounted 1/2 wavelength high), but the impedance of a 2 wl loop is about 83 ohms when corner fed or 285 ohms when mid-side fed. Either of these impedances is easily matched. One of the really great things about these loops is that the impedance is low to moderate at all harmonics, not just at odd harmonics as for linear verticals and dipoles. Note that the feed impedance will vary with height above ground just like any other horizontally polarized antenna.

A 1 wl loop will have about 6.3 dBi gain (at 1/2 wl height), with a broad bidirectional pattern with side levels about 6 dB down. SWR bandwidth is 320 kHz (not an issue on 30m). Side or corner feed produces essentially the same pattern, just rotated 45 degrees.

A 2 wl loop will have 7.6 dBi gain in 4 directions, when mid-side fed (4 shallow nulls about 7 dB down). SWR bandwidth is 680 kHz, about twice the 1 wl loop. If corner fed, the gain drops to 6.5 dBi, but the dips between the four lobes are only about 4.5 dB down. The SWR bandwidth with corner feed is much narrower, only about 200 kHz.

Like any other design activity, you have to decide what configuration fits your situation best. It's always good to understand your options. I'll be glad to share my EZNEC models.

Thanks ACE,

Check my math. For the single freq of 10.150 I would use 15.99 feet
of 75 Ohm. It is another 15 feet to get into the Transceiver. I
would use 50 ohm coax for that. I will not use any other freq other
than 10.150.

I was going to put this about 5 feet above the roof(25 feet above
the ground. Would there be a problem using 1/4 copper tubing in
place of wire? Receive(low noise) is more important than xmit.

Thanks again
Roger

The chart is for a 15m vertical antenna . I should have said "Here is
a chart showing the Mismatch Loss to Frequency relationship of an

antenna that is resonant at about 5 Mhz . A vertical antenna that is 15m or 49.5 feet will be a 1/4 wave antenna that resonates at 4.7272 Mhz .
15 mtrs = 49.5 feet .

I have had a 1 wavelength loop , a 2 wavelength loop , and a 3 wavelength loop up , all were for the 160 meter band . Any gain difference was unnoticeable . A 3db difference is said to be barely discernible . It was definitely not worth the extra wire. Experience is a good teacher.
Anyone with a full wave loop can measure the SWR at the design Frequency , Then Double the Frequency effectively making it a 2 Wavelength loop, and measure the SWR again.
I just did this simple test . As a one wave loop the SWR is 1:1 , as a 2 wave loop the SWR jumped to over 4:1 . Try it yourself.

And Yes , It is usually pretty easy to match most antennas with a tuner .
But if I were making an antenna
"for the single freq of 10.150"
I would not want or need an antenna tuner.
I stand by my original statement
"I would put up a Full Wave Loop. 99 feet of wire in a square with 24 feet 9 inches on each side .
I would NOT make the loop 2 wavelengths. If you make it 2 wavelengths it will have a high VSWR at 10.15 Mhz"

Roger,
Your math is right on . I would use 16 feet of NON foam dielectric
75 ohm coax . 1/4 copper tubing will work great . Loops are very
quiet antennas.

>15 mtrs = 49.5 feet .

My only point was that your chart showed very high mismatch loss at even harmonics, which isn't the case with a loop. Skywire loops have high mismatch losses at frequencies where the loop is about 1.5 wl, 2.5 wl, 3.5 wl, etc., which are normally between the ham bands.

(Note that a 4:1 SWR produces only a potential 2 dB mismatch loss, although this is only important for wideband receiving applications where no precise impedance matching is used.)

>I have had a 1 wavelength loop , a 2 wavelength loop , and a 3 wavelength

It will depend on the azimuth to the station you are working. Off the "side" of a 1 wl loop pattern, the signal may be down about 6 dB, which can be noticeable. (Loops at heights below 1/2 wavelength will be more omnidirectional.) A 2 wl loop will have about the same gain at all 4 of the 90 degrees points. It will also have less response to NVIS signals and noise due to the pattern null at the zenith.

>Anyone with a full wave loop can measure the SWR at the design Frequency ,

I'm sure you are right. This is partly because the 1/4 wave line used for matching is a half wave at the 2nd harmonic and doesn't do any transformation there.

>And Yes , It is usually pretty easy to match most antennas with a tuner .

Or a 4:1 balun or a "series-section" match on a single band.

>But if I were making an antenna "for the single freq of 10.150"

That's certainly a good approach, simple to match, and definitely takes less real estate. However, the VSWR isn't a problem if you use a matching arrangement that accommodates the feed impedance, just as you have done for the impedance of a 1 wl loop.

Is there an optimum height above ground for the single operating
freq of 10.150?

Thanks
Roger

> Roger

You said you wanted a SINGLE FREQUENCY 30 meter loop.

I might put it up as a vertical delta loop
fed at the bottom with a balun.

There was an article in Sprat/Qrp Quarterly
describing a "Quiet 30m Antenna" vertical
delta loop.

It was 3x33.1 feet around (99.3 foot loop)
It had a choke/matching section made out of 17 feet 4
inches of rg59 (75 ohm coax) at the bottom
corner and was supported at the top two corners
by two ropes into two trees.

If you can get the horizontal top at 55.5 feet that
looks to be the highest gain but the higher you go,
the lower the take off angle.

It will NOT work as well on other bands in the vertical
configuration as it would if it were horizontal but
it will work very well on the design frequency.

Some other reading on loops:

http://www.cebik.com/vdelt.html

http://www.qsl.net/wd8rif/text/looper.txt

http://www.qsl.net/wd8rif/text/delta.txt

http://www.qsl.net/wd8rif/text/40mloop.txt

http://www.qsl.net/wd8rif/text/w6rca.txt

http://www.qsl.net/wd8rif/text/40m_rect.txt

http://www.qsl.net/wd8rif/text/loops.txt

If you really want a skywire (horizontal loop) then
I would go with "big and high" and a tuner/ladderline
and dont worry too much about the swr on the feedline.

Topic: 403 Message: 403

Hello everyone,
I'm new to the group.
I am curious to know if anyone has any experience using a tuning stub on the loop.
I am currently feeding it with RG8 and the auto tuner on one of my rigs won't tune it for 75 meters. The resonant freq of the loop is 3530.
I am considering using a stub of RG11 (75 ohm) coax cut to the resonant freq.
My concern is that it will alter how well it tunes on other bands.
Anyone have any experience with this?
Thanks in advance,

Rick

Hello everyone,

I've been running a 280 foot loop for almost 2 years
now.
Since I went from balanced line to RG8, it is stubborn
to tune on 75 meters, my rig's built-in tuner, won't
tune it.
I have been considering making a tuning stud out of
RG11 (75 ohm), but I'm concerned that it will degrade
the performance on the other bands (the loop is used
for 80-10 meters).
Anyone have any experience or ideas on this?

Thanks,
Rick

405. Load Coil Re-visited

Yahoo group: SkyWires
Date: 2004-03-08 20:58:12 UTC
From: Michael
Topic: 405 Message: 405

Just passing on what I found.

I put up a 5 foot long coil on 2" o.d. pvc with
118 foot of #12 insulated wire didn't do any
calculations or tests on values. I just put it up,
and used it.

What I found:

1. Tuner is easier to tune on 160 and 80 meters,
a lot harder to tune on 40 - 10 meter.

2. Heard people on the noontime net that I had
never heard before. I was also able to speak
to them after the net.

3. Signal reports from friends opposite the load
coil went up an average of 1/2 to 1 1/2S units.
Friends on the same side as the coil (S.S.W.)
went down by 1/2 to 3/4 of an S unit. Xmit and
receive.

In all not bad.

Worth the trouble for me?
NO

More wire up in a larger horizontal loop?
Yes, that is what I'm doing this coming weekend !

And YES the coil is being pulled out!

Did it work well with balanced feedline?
If so, I would go back to that unless you
have a strong reason not to.

Answering your question though,
I did have a 40 meter with a 75 ohm matching
section that worked well for me through a
tuner on 40 through 10 ("NoviLoop")

I am however a fan of balanced feedline and
would go back to that given the choice

Rick
I fooled around with all kinds os feed lines, But ladder line is by far
the best for me.
i have a 840' loop and feed it with 450ohm to a tunner and it tunes
good from 160 to 10.

408. Re: [SkyWires] Re: New member

Yahoo group: SkyWires
Date: 2004-03-10 00:20:03 UTC
From: Rick Henderson
Topic: 404 Message: 408

The balanced feedline worked VERY well till I tried to use a linear amp with it. It cooked my 2kw balun (4:1 current) after only a few transmissions...cheap balun.

The majority of my 100 ft transmission line is near my aluminum siding or in my house. So went back to coax.

I can tune and operate full power anywhere 80-10 meters with my Heath SA-2060A tuner...not a problem there.

But, I sometimes like to run my newest xcvr direct to the antenna and use the internal autotuner. Very convenient! This is where my problem arises.

The antenna is resonant on 3540. The autotuner will not tune any freq on 80/75 meters above 3700....so that tells me that the antenna is a tough match there. Also on 30 meters...the autotuner will only let me run about 20 watts at 1.3 to 1.

I am feeding my loop through 100 feet of RG8 now. I am going to replace the 50 ft section at the antenna end with a 50 ft piece of RG11 (There is a formula that gave me 47.8 feet for a 75 ohm stub for 3540). Now, I am hoping that this will help the autotuner do 75 meters, and I am sure it will.
But I am also hoping that the rest of the bands work just as well as they do now.
You are right though...the balance feedline works the best, but my set up here just doesn't allow the freedom to use it. The feed point of my antenna is only 35 ft away from the second floor of my aluminum sided house and there really isn't enough room to take it anywhere else. I have found that the longer the feed line, the easier the tune too.
Thanks for the input, and I'll let you know how it works out.

412. Balanced Feedlines...

Yahoo group: SkyWires
Date: 2004-03-10 01:10:38 UTC
From: JimMcSkate@aol.com
Topic: 409 Message: 412

Once I figure out which button on this ^&^#&@@ laptop means "SEND" I think I'll hack it out with a butter knife ;-)

I've been having great luck with my 40m loop fed with balanced line. The original article on Loop Skywires called for coax (RG58) which today would seem to be a poor (lossy) choice.

This is a question for those folks who go back a while in this hobby: Was there a time (late 1970's?) where coax was king, and balanced line was considered old fashioned? I got my ticket in '77, and there seemed to be nary a mention of balanced line for transmitting purposes, and the 300-ohm twinlead was just used for TV antennas. I think if Dave Fischer wrote his article today, he would've suggested balanced line first.

Just a theory...

My loop is fed with 30 or so feet of 300-ohm twinlead straight from Radio Shack (for those outside of North America, Radio Shack is a chain of consumer electronics stores that still manages to keep a corner somewhere with resistors and chips and connectors. Like McDonald's franchises, they are all laid out the same way, and in that far corner you usually find, well, folks like us. In fact, I've come to call it the "Geek Orthodox Church".)

Have a great day, everyone!

Rick
It is up at 42' (about) I have a bobcat and do a lot of postholes so I put three long poles up , and I have two towers so that is what keeps it up there.I also have a lot of space here to work with.
It sounds like your on the right track with yours, let me know how it works on all bands.

Hi All,
I also have ran loops for several years. I agree with Rick , I tried one , two and three wavelength loops on the 160 meter band . The only difference I could see was that it was harder to match the two wavelength loop to coax.
I am currently using a 75 meter full wave delta loop.

423. shortwave radio is in trouble

Yahoo group: SkyWires
Date: 2004-03-25 21:49:17 UTC
From: Stephanie
Topic: 423 Message: 423

The following is an URGENT plea to all shortwave radio listeners, ham radio operators and anyone that has an interest in the shortwave radio spectrum.

BPL - Broadband Over Power Line is a new form of broadband internet service being deployed by Electric Utilities around the world. BPL uses the shortwave radio spectrum to deliver internet service over their power lines to the home. In field trials thus far conducted around the world, BPL causes severe interference to shortwave radio reception. Japan and The Netherlands have concluded that BPL is too great a threat to the shortwave radio spectrum and have banned its deployment. The electric utilities deny that this service causes interference to shortwave radio reception.

A typical scenario just to give you an idea of how much a threat BPL is - Part 15 governs BPL deployment and Part 15 does not adequately address our concerns for the prevention of interference. Part 15 states that the hard limit is 30uv/meter at 30 meters (98.4 feet). According to W1RFI, this type of signal at 3.5 MHz will produce a S-meter reading of S9 +16 when using a dipole antenna. Clearly, an issue for most shortwave radio spectrum users that live close to power lines in their neighborhood.

You must investigate the following links:

ARRL Power line Communications information page
http://www.arrl.org/tis/info/HTML/plc/

W1RFI's excellent technical presentation on BPL
http://www.arrl.org/tis/info/HTML/plc/BPL_Presentation.htm

Observe this threat for yourself and then file your comments on FCC Notice of proposed rulemaking for Dockets 03-104 and 04-37. The comment filing window is only 45 days and is already ticking away. File your comments now.

Downloadable copy of FCC Notice of proposed rulemaking
http://hraunfoss.fcc.gov/edocs_public/attachmatch/FCC-04-29A1.doc

Please understand that your comments made on this NPRM must demonstrate to the FCC that BPL must avoid using the shortwave radio spectrum. It is very easy to file comments online.

Follow Broadband Over Power Line (BPL) - Docket 04-37
http://gullfoss2.fcc.gov/ecfs/Upload/

Comments from individuals are needed to let the FCC understand there are lots of shortwave enthusiasts out there who choose to listen to HF broadcasts without interference from BPL.

Please forward this email message on to inform others of this impending threat.

424. 80 Meter Loop

Yahoo group: SkyWires
Date: 2004-03-26 13:24:15 UTC
From: craig_mohn
Topic: 424 Message: 424

I have had great results with my 80 meter loop.
It wount work on 30, 12,17, 6 or 440.
It does work and works well on 2 meters.
I'm glad my backyard is not any smaller. Height varies from 30 to 7 feet.
Hope to work you all!

73 Craig, KA3ICJ

Hello to the group:
I want to try a new antenna, and was considering a full wave 80 meter loop or a long wire. Because I can only put it up about 20 feet, I am not sure which to go with. I modeled both on MMANA and the loop is a cloud burner, and the long wire shows a better take off angle and as much gain. Any help would be appreciated. I would like a loop for it's quite operation and multiband use with a tuner. What do the experts think???

Takeoff angle is high on 80, but lowers on the higher bands. I have a 40m loop up 18 feet and I consider it the best antenna I've ever owned - just this weekend I've worked as far south as Argentina and as far west as Siberia, and all sorts of places in between... on 10, 15, and 20m phone running about 75 watts.

You'll love the loop. It's the most underutilized antenna ever invented! Plus, it's cheap - if you don't like it, keep the feedline and straighten your loop into a long wire... you'll go back to the loop soon enough.

Check out mine on www.qsl.net/wa2lgn

One thing I would add, I find it to be a slightly quieter antenna in the noise department too.

Dave N8PU

P.S. Mine is a 160 Meter loop that isn't more than 12 to 15 feet above ground and I have good results (for me) with mine.

I would recommend the loop, even though it LOOKS like
a cloud burner, I work all over the northeast on 80
mtrs phone during the day and as far south as Florida
at nite. I've worked Europe many times at nite on 80
cw (All barefoot!) It's awesome on 20-17-15-12-10 for
dx too.
I love my 80 meter loop!

Dan, Best wire antenna I've ever had.

I agree with the others who have mentioned take off angle is high on 160 and also 80 but becomes a better DX antenna on the higher bands. Mine is a 1000' at between 30' and 35' up in almost a square shape fed with commercial ladder line terminates into a 4:1 balun and into the shack through RG-214 coax (because I had some) into a Dentron tuner, works all bands, easy to tune and is quieter and some signal increase over my 80 Mtr dipole at 80' (Inverted Vee) I cannot say enough, been licensed since 1955 and truly this is the best antenna I've ever put up, reasonable in cost, easy.....

Go for it, you will be proud of it.....Mac

430. 40M loop has impressive 20M performance.

Yahoo group: SkyWires
Date: 2004-04-03 03:40:01 UTC
From: nc9k
Topic: 430 Message: 430

I'm impressed with the Skywire Loop and this discussion group. Thanks for all the postings on this antenna. One of the main things I learned from postings here is to operate the Skywire Loop on its harmonics, and not fundamental in order to push the angle of radiation down for DX work.

I became a SWL in 1969 at age 9, using a 30 tube E.H. Scott receiver and an 18ga 120ft. "magnetic loop" antenna wrapped around my grandparents' house where I lived. This antenna had been recommended to me by a neighbor who had himself been a SWL since WWII. The reception was wonderful, and impulse noise was never a problem. I joined Wis. Civil Air Patrol, got involved with its 75M net as Badger 205 in 1974, and eventually became net control because I could "hear" better other stations with my double extended Zepp up about 50ft. fed with homemade 14ga 600 ohm ladderline. My grandparents didn't have trees in the right spots to get a "magnetic loop" up to replace the Zepp, and I wasn't about to feed my Desk Kilowatt into the 18ga SWL loop wrapped around my grandparents' house! I got my First Phone with Radar in 1976, and became Chief Engineer at a number of broadcast stations around Northern Illinois. I got my Ham ticket in 1984 with my present call. Enough background.

I've experimented with numerous antennas for shortwave receiving, including hooking up and tuning an insulated base 550 ft. commercial broadcast tower at night just to see how it would receive on higher bands.

I'll tell you what, the simple 12ga 135 ft long Skywire Loop I just erected at 40 ft. on 4 trees, fed with 450 ohm ladderline into the antenna tuner I built from scratch 30 years ago "hears" better on 20M better than any antenna I've tried over the past 25 years, including most recently a 204 ft G5RV! This Skywire Loop tunes properly on 40 through 10M. Listening to 20M nets all day today, I was copying stations trying to check in that most if not all stations in the various nets could not hear. European stations were pegging my S-Meter!

My next project will be to erect a 320M long Skywire Loop for use on 160M through 40M sometime this spring. I just have to find the right combination of trees. Thanks again for this Skywire group.

431. Two (or more) feedpoints?

Yahoo group: SkyWires
Date: 2004-04-08 13:44:27 UTC
From: cpa2000
Topic: 431 Message: 431

Many of us use 1 wl horizontal loops configured in a rectangle like shape.

When these loops are operated at frequencies greater than the fundamental, the horizontal pattern changes.

For example, if we operate a 1 wl, side fed, square, 80 meter horizontal loop on 40 meters, the horizontal pattern is that of a cloverleaf with four major lobes and four nulls.

Now this is great if you intend to QSO with a station in the direction of a lobe but not so great if your target is in the direction of a null.

Now if I move the feed point to an adjacent side of the loop, the lobes & nulls change places. In essence, I "rotate" the pattern by moving the feed point.

I have attempted to take advantage of this shift in pattern by erecting a 160 meter loop that "floats" in pulleys at the corners. I then tried to physically drag the loop wire through their supporting pulleys & move the entire antenna wire until the feed point was where I wanted it. This has not really worked out due to the weight of the wire, binding at the pulleys & other mechanical problems & I have abandoned this idea.

I'm thinking now that I should just add a second feed line on a side adjacent to the original feed point and simply select the feed line (and pattern) that suits my operating needs.

My problem is that I'm not sure of the effect of adding that second feed line. Should the unused feed line be grounded or simply left unconnected at the transmitter? Or should I use relays at the feedpoints to "jumper" the unused feedline?

My goal is an antenna that covers 160- 17 meters, has "gain" on the frequencies greater than 2.0 mc & that has a way of shifting the pattern on the frequencies greater than 2.0 mc.

Any help, comments will be appreciated.

Tnx

Terry

Thanks Jim, for another good option. It begs the question; how much separation between the loops?

Anyone with modeling software out there that can give us the best route to take?

It may just come down to cost (the extra wire/insulator cost vs the cost of the relays)

I just posted a file to the "Files" section of this group.

It is the H (horizontal) pattern of an 80 meter, 1 wl, side fed,
square loop @ 7mhz. Note the "4 leaf clover" pattern that develops @
twice the fundamental frequency. The 4 lobes & nulls switch positions
when the feed point is moved to an adjacent side.

It would be easy to use say two relays at two diffrent points that can get there power throught the feedline. Placment is up to you as to how far appart to place the relays. As a part of the loop between the relays I would run RG-58 coax for it's weight and has very low loss at HF frequencys. I would use the shield of the coax as a part of the loop. The relays would be set up so that with no power applyed the loop feed point would be at the relay where the coax would normally feed the loop. That relay would be open and the relay at the end of the coax would be closed so it not breaking the loop. When DC power is applyed to the feed line it would power up both relays and the normal feedline relay would close the loop at that point and the relay at the end of the coax would open the loop and feed it with that end of the coax. Using the shield of the coax as part of the loop will make no diffrence to the center lead of the coax. You will need to have a DC blocking capacitor at the transmitter and at each relay feedpoint of the loop as a loop is a DC short. You will also need an inductor at the relay DC supply to keep the RF during transmit out the power supply and also one at each of the relays coils to keep it out of the relay coils. Each capacitor will block DC voltage to the antenna and transmiter. The inductor will block RF voltage from the DC power supply and the relay coils. I hope this helps with your project as it would be cheap to do it this way.

Hey Dan!
Cloud burner? Ain't software great!
I would like to suggest you give it a try - the skywire that is, not the software. I think you will be pleasently suprised.

After 1,000 contacts, take it down and put up the long-wire. Send me an email to let me know how you like that one.

Friends are very happy with their Carolina Windom....

I am about due for a new hunk of wire and need to decide myself.
Keeping the loop though it outperforms my G5RV - with apologies.

Hi Bryan,
I have a 840' loop and like you I use 450 ohm feedline, however I do run mine direct to the tunner in the shack, I never thought that rf was a problim on hf but maybe I am wrong. I ground my tunner and radio to a 10' rod just out side the shack, I found it tuned better after I but the ground in. However that wont be any good for lightning , I will need something more for sure. This should help some with static though.

443. Re: loops and grounding

Yahoo group: SkyWires
Date: 2004-04-16 05:01:24 UTC
From: nc9k
Topic: 440 Message: 443

Hello Keith and Bryan,

I've learned over the years that the best lightning protection for a home system is a complete disconnect of the station equipment from the antenna system with concurrent grounding of the balanced antenna transmission line feeds outside the building. I use a very large mil-surplus dpdt RF knife switch located just above a copper ground rod system. I also use a pair of 100k ohm static bleed resistors outside the building from each balanced feedline to ground. Your RF feed through the station wall should be of a non-flammable material like ceramic or glass tubing, etc.. You should also use high capacity AC power surge arrestor (with built-in telephone line surge arrestor if you have an online station computer) in your station tied directly to your station ground.

One of the things to remember is to discourage secondary lightning groundpaths leading through power cords, modems, transformer windings etc. inside the building. It is best to apply the concept of "star grounding" which means one common extremely low resistance - low inductance grounding point outside the building that all station equipment ties to directly through individual heavy busses (if possible). Then if a direct strike does originate at your station (lightning travels from the ground upward) all your equipment remains at the same electrical potential relative to each other and the AC feed and overvoltage conditions do not occur. Any high amperage lightning currents flow outside of and away from the building thus reducing the chance of fire. I used the above techniques (minus throwing the knife switch) while operating a double extended Zepp on 75M during electrical storms as a net control station. While operating I would experience the occasional lightning induced static flash across the plates of the balanced capacitor in my homemade antenna tuner. After net signoff I would throw the knife switch and not worry. I never lost any equipment. I am currently using this technique with my Skywire loop.

From my commercial broadcast days the lightning control solution for tall insulated base AM towers (which were always experiencing direct lightning strikes) was to use 2 inch diameter copper balls spaced 1/4 to 1/2 inch from each other (depending on peak RF voltage present) at the base of each tower on heavy arms as a lightning sparkgap. Then the 1/4 inch tubing feeding station RF into each tower base would be formed into a 3 turn loop with a 12 inch diameter, with about 2 inch spacing between each turn. I would do the same with the coax feeding repeaters and studio-transmitter links on these towers. I never lost any equipment using these techniques.

I hope my experiences give you some ideas.

Leland - NC9K

444. Additional lightning info

Yahoo group: SkyWires

From: nc9k
Topic: 444 Message: 444

I realized I have to mention that I use an inductive RF coupling-impedance transformer in my homemade transmatch in order to eliminate a direct dc path from the ladder line to the trancsceiver input. I also use high tension teflon coated wire for the primary turns in the transformer. Lightning would be common mode on the transmission line and therefore not inductively coupled through the transmatch. The issue then becomes voltage breakdown between transformer primary and secondary windings (along with minor capacitive coupling), hence the teflon coated wire.

Concerning possible lightning on the ladder line, I use adjustable spark gaps from each conductor to ground outside of my building.

I have a Horzontal loop up about 35 feet cut for 75 meters and I am feeding it with 450 ohm ladder line. This things play wonderful on 75 and 40. And seems to do ok on the other bands compared to my vertical.

Here is my question and would like to see if anyone else has this issue? I am on 15 meters right now and with my skywire loop I have a S8 noise level. With my Gap Titan Vertical I have a S1 noise level. Tuning across the band I come across a station who is peaking 10 Over on the Skywire and S8 on the Gap.

I see this on 60 meters, 15 and 10 meters just a very hig noise level. Not real sure if it is picking up a horz polorized manmade noise or what?

Any ideas?

Scott

Scott,
My problem is on the low end of the band, 160 and 75, but in my case it is caused (on 75) by my computer (160 I suspect is just 'normal' noise), it is setting next to my older TS-430S radio, anything at my QTH 40 Meter and up is quite in the noise department with or without my PC running.

Just a thought, what electronic device(s) do you have near your radio that might cause interference; if any you might try and experiment, if you haven't already, try and turn off all devices and see if your noise goes away.

I am running RG-8 from the wire to my tuner and two (2) RG-58 2 foot jumpers from my radio to the tuner and from the tuner to the external SWR Bridge that stays inline all the time, since neither my tuner nor the radio has a built in SWR meter. The wire is maybe up 30 feet at the highest and down to 10 feet where the coax is attached. Just a side note, my wire will not match any where below 3 to 1 without the tuner, that is why I leave every thing in line all the time.

Good luck in chancing down that noise.

Hi Scott:

I don't have a horizontal loop antenna with which to compare notes; I just have some observations. I assume you do not experience the poor S/N performance on 75 and 40 mtrs.; only the bands higher in frequency have the poor S/N ratios. I also infer that the xmit performance at the higher frequencies is as good or better than the vertical.

- is the loop intact? eg. be sure it is not broken somewhere and performing as a long wire antenna of some sort.

- perhaps the bandwidth of the loop is very broad at these higher frequencies. S/N is related to bandwidth.

- if xmit performance of the loop is superior you may consider xmit on the loop and receiving on the vertical. After all a 26 db reduction in the S/N ratio is nothing to sneeze at. eg loop 64db - 48db = 16db S/N vs vertical 48db - 6db = 42db S/N.

HI Leland,

Indeed thanks for the ideas concerning lightning control.. my home/station sets atop a hill over looking the city by about 100ft so if we get a strike it usually is close by. (with in a block or so of home QTH)

I will definately look at the grounding ideas more.. I currently use a solid #6 copper wire posted on cermaic insulators along the backside of the ham bench. this #6 wire goes outside and is attached to a 6 ft ground rod about 3 feet away from the side of the house and driven deep. I use lightning arresting pl258 connectors and a wire attached to an alligator clip that gets clipped on when the station is not in use.. I figure it just drains off static..
(this has been my dipole policy in the past) the new SKY LOOP is about 490 ft and ranges from 12' to about 45' up in several places... it is strung 1/2 of it through a wooded area. ill be curious how it fairs in storms and from lightning.

I used 450ohm ladder line and and then put a 20 ft r213 pigtail to bring it into the shack. << this being 50ohms or there about.. I did a ohm meter check on the circuit while not attached to the radio.. it was 158ohms before It goes into my MFJ 300watt tuner with artificial ground. the skywire seems to be a quiet listener.. im hearing things i never heard on the dipole..
with the tuner I get a breeze of a match. im curious how it will talk.
anyone with suggestions or ideas.. keep them coming.. the sky loop concept is very new to me..
by the way for the information of all.. I used stainless steel wired coated with vinyl its about 2-3mm thick with coating.. found it last summer on Ebay... I implimented the bungee cord Idea on the stress points. and I think it will do well.

73's Bryan Kc8hps Thanks for listening!

Bryan and the group,
When I check my resistance at the connecter where I screw it into my MFJ 300 watt tuner, I only get about 2 ohm (with a digital volt ohm meter), I was wondering if your result had any thing to do with the ladder line. I have my RG-8 coax soldered directly to the 12 gauge wire. I am using about 530 feet of wire; I don't know if the loop should give me a good SWR, less than 2 to 1 match WITHOUT using my tuner, but my set up does not. On 160 and 75 it is a son of a gun to tune a good match, I can do it but it is very fussy and on those 2 bands I can only move about 20 KHz or so before thinking I want to re-tune, now maybe I don't need to retune that often but a 2 to 1 match is not acceptable to me. When I get to 40 and up (except for 10) I can get just about the whole band without needing to readjust my tuner; My SWR meter stays in line all the time since my tuner does not have a SWR meter in it.

Those of you that have had a loop for several years maybe could let me know if my results are about average, the wire is house gauge #12, so it has the plastic coating on it, but the wire is strung in the trees against the trunk of the tree on the corners, the configuration of the loop is sort of a delta in its shape. I do like the way it works once I have it tuned, as others have said it is a quite loop.

Hello David and the Group,

I dont know but I would assume its the ladderline that give me the 158ohms.. I do know it tunes real decent all over the place and the kicker is I have LOW NOISE and great ability to hear.. I have been listening to the weather net on 80meters for area 9 wisconsin. those guys are booming in like nobodys business.
im talking nearly full scale.

I think the combo of ladderline and the RG8 213 give me the ohm reading.. just as a side note I use a digital ohm meter as well.. boy I like that thing

Hi Bryan,
I suspect your ohm meter is reading 158 ohms because you are using
stainless steel wire instead of copper wire.

wh2t and the Group,

Yes I think your likely right about the stainless steel.. I never stopped to think the resistance could be that much higher using that vs. copper wire. I know one thing I think it will be stronger than the copper was, and I just hope its as good of a talker.

Hello Bryan,

I preume you hit ledge rock with your ground rod being only 6 ft. down. If so, you need to have at least 3 ground rods spaced 5 to 10 ft. apart and connected together with # 4 or larger copper wire to get an effective ground for lightning control.

My 135 ft. 40M loop is contructed of # 12 housewire, and has a measured dc resistance of 0.2 ohms. My 75 ft. of commercial 450 ohm hard drawn # 18 copper wire ladderline has a measured dc resistance of 2 ohms. The entire antenna free-floats through electric fence corner insulators up on 36 inch UV resistant bungee cords.

Your coaxial pigtail has minor dc resistance, as does your ladderline. Your stainless steel small gauge antenna wire is contributing close to 155 ohms of dc resistance, and likely much higher RF resistance because of skin effect losses.

12 soft drawn copper wire has a dc resistance of about 1.6 ohms per 1000 ft. If your antenna were constructed of such wire it would have a dc resistance in the loop of about 0.8 ohms. The ARRL charts indicate soft drawn copper wire has a conductivity of 100, hard drawn copper wire 87, and steel wire between 3 to 15. Loop antennas 1 wavelength or longer have sizeable current loops. You are giving up a great deal of transmitter power because your small conductor stainless steel wire antenna is akin to nichrome wire in conductivity, especially in light of very high RF skin losses associated with thin steel wire. Maybe you could use your stainless wire to "fish" through # 12 copper wire as its replacement to reduce your antenna losses.

Concerning your coaxial "pigtail", one of the nice things design-wise about a loop antenna (being mainly magnetic) is that in their balanced form they do not respond much to common-mode electric fields from things such as noisy powerlines. My loop system is entirely balanced, the loop feeding 450 ohm ladderline into my inductively coupled balanced input antenna tuner. The availability of trees for my loop unfortunately places one section of my loop within 75 ft. of a somewhat noisy 13.6 KV powerline. With my balanced system I do not hear any noise from this powerline on my FT 101B. I do not use a NB or ANL either. My receiver S meter comes up about 1/2 S unit with 20M sky noise "hiss" when I connect the loop. This "hiss" level varies with band conditions, going up somewhat when the band is really open, and almost completely disappears when the band is weak.

I tried an experiment with grounding one side and then the other of the ladderline input to my tuner. When I grounded the ladderline conductor feeding the side of the loop furthest away from the powerline I suddenly had powerline interference and it was very annoying. I then moved the ground clip to the other ladderline conductor and the interference was about half as bad. Retuning the tuner under these alternate grounding conditions did not make the interference go away. The interference again was completely gone when I stopped grounding either conductor.

What I conclude from this simple, yet telling experiment is stations using coax connected to their loops, or ladderline that eventually feeds coax going into a station, are losing the common-mode electric field interference rejection benefit that a loop antenna is capable of offering. The importance of this would vary from station to station.

Hi Leland:

I found your comments very interesting, especially the effect of keeping a 'balanced' antenna such as the loop completely balanced. I do not know if there is a significant difference in performance from the transmitting point of view but I agree there is a significant difference from the receiving point of view. I do not have experience with a large horizontal loop eg full wavelength on 80 M for example, but I have used a full wave vertical loop on 20M, eg a quad and also small, 1/10 wavelength receiving loops.

In the first case, the 20M 1 wavelength loop, (quad) antenna, I have used coax feed to an unbalanced tuner, balanced feed (300 feed line) to an air core balun and then to a unbalanced tuner, the same system with a ferrite balun, and finally a balanced feed (300 ohm) to an inductively coupled balanced tuner. In all cases I was able to achieve satisfactory stable power transmission. However, on reception only the last arrangement (balanced loop, to balanced feed line, to inductively coupled balanced tuner) managed to reduce the local EMI. Every time I introduced coaxial cable I also significantly increased the noise from EMI ! Now that is contrary to what everyone tells you !

My experience with small 1/10 wave length tuned loops is for reception only. I tried a lot of different small antennas for SW broadcast reception in a rather noisy and space limited environment (apartment block balcony), and soon concluded that the loop was the best bet. I started out with tuned loops made from coaxial cable and soon found tuning limitations due to the inherent capacity of the coaxial feed line. This limitation dictated that the antenna tuner needed to be close to the loop. I then experimented with using a simple wire loop fed with 300 ohm line to a balun/antenna tuner. This provided a quantum leap in performance and allowed the tuner/receiver to be located together in a convenient location. However, just by accident I replaced the balun/tuner arrangement with my old inductively coupled balanced antenna tuner and was impressed with the additional noise reduction and improved loop null.

My conclusion from this experience is similar to yours:

- noise reduction of a balanced antenna is due primarily to the fact it is balanced and has less to due with orientation.
- feeding the antenna has 2 major factors ..... impedance match for transmission, and maintenance of balance for reception.
- coax feed is not a 'no brainer'!
- the ideal situation is a balanced, low loss, feedline fed directly to an inductively coupled balanced antenna tuner (commercial units are rare).
- if you use an unbalanced antenna tuner the kind of device used to convert 'balanced' to 'unbalnced' eg "balun" is important from the reception perspective. For reception purposes I find RF transformers wound on ferrite or powdered iron cores with complete isolation from ground on the antenna side works just fine.

Now how could it be more simple than running 300 ohm feed line directly from the antenna to the tuner, with NO connection to ground! Use an ohm meter to check. I know we are not dealing with DC but RF .... however, it will affect antenna balance. Such an arrangement will handle a standard 100 W transmitter with good electrical and mechanical efficiency.

I have put up a 600 ft loop of 12 gauge copper suspended from 32' lengths of 2" aluminum irrigation pipe. I am currently feeding it with about 50' of 450 ohm ladder line into a radioworks 4:1 remote current balun. I then have a short run of rg-8 into an old kenwood at-120. The loop tunes fine on all the bands available on this old tuner (80/40/20/15/10) and is about 2.5:1 on 160 straight through. The average height above the ground for my wire is around 30' over shale/rocky terrain. Some points are probably 35' while other may be as low as 25'. I am questioning the length of the ladder line at 50' and am wondering if it should be longer or ? Also, with the loop being theoritically resonant at 1.67 hz (formula only, to be verified with an analyzer soon) am I shooting myself in the foot ie should I shorten it to 1.8mhz while we have the analyzer on site ?

Great group ! Wish I had found it before putting all the hardware in the air...

Hi Mark,

I found by experimentation with my 80 meter loop that everthing is happier with at least a quarter wave of ladder line before the balun.

The "happy" frequency of my 280 foot loop is 3.540 mhz and I run just over 68 feet of 450 ohm to a DX-Engineering 4:1 current balun and then 50 feet of RG8 to and into the house. I actually run the feed line a longer distance than necesary in order to fit the extra ladder line in.

With shorter lengths of ladder line, it tuned "oddly" at some frequencies. Especially the top end of 75 meters,and sometimes 30 meters.

Now it is a happy camper on all frequencies, 80-10 meters. Loads up pretty well on the lower end of 6 meters too!

I've been playing with this loop for about 2 years now and highly recommend it as a great all around antenna.

73's and good luck!

I have a question to any one in the group that uses only coax to attach to their loop, does your loop (mine is about 530 feet long and about 15 to 20 feet above ground looped around trees at the corners making a delta shape, sort of) tune on ANY frequency without needing the tuner to get your SWR below 2 to 1? Mine is the toughest to tune on 160 and 75 Meter, my set up doesn't seem to have a "happy" frequency any where, just wondering and thanks. It still makes a good and quite DX antenna.

Thats a tough match Dave. I tried using just RG8 for
mine for a little while (about 100 feet of it) and
there were several frequencies that my auto tuner
would NOT tune, and my big old SA-2060A tuner even had
a hard time with some of them.
I finally made a quarter wave matching section of 75
ohm coax and that helped quite a bit.
My happy frequency was the "resonant" frequency of
3.540, and the best swr was there, at 1.5:1. I never
got around to checking the swr of the harmonics but it
tuned easier on the harmonics.

From: Scott Erwin
Topic: 455 Message: 459

Here is the trick, add a little coax or take a little coax away. This will change the SWR for any given frequency at the end of the coax feed line. The loop is not a 50 ohm match on any band unless you make the 1/4 wave times velocity factor 75 ohm coaxal matching transformer for the band it's made for. This transformer will give a good match to amy length of 50 ohm coax close the it's cut frequency. After that you have high and low SWR peaks and dips along the coax line. If you have a length of 1/2 wave times the velocity factor of the coax used the SWR will be exactly the same at each end, and something else in the middle if it's not connected to an exact 50 ohm match. So the trick is to add a few feet to the end untill you have a close match at the end of the coax for the bands you operate on. Putting in that few feet will change the SWR readings on all the other bands. If you use 450 ohm ladder line even a foot or two will make a big diffrence. One trick with ladder like was to form a loop in the ladder line a few feet long with a relay connecting or disconnecting the added feed line length. This would allow changing the feed point impedance at the transmitter end of the line. The same could be done with coax. Just remember, your not changing the antenna impedance, just the SWR at the point where the antenna tuner or transmitter is connected to it.

From: Dr.Ace Ratliff
Topic: 455 Message: 460

The impedance of a Full Wave Loop antenna is theoretically in the vicinity of 100 ohms. That is why I use a 75 ohm "Q section" to provide a perfect match to the 50 ohm coax. My 260 ft Horizontal Loop antenna is flat 1:1 VSWR around 3.875 Mhz and rises to about 2:1 SWR at 3.75 and 4 Mhz . So I cover the entire 75 meter phone band without using a tuner.

Here is How I Do It.

Connect the shield of a "Short Piece" of 75 ohm coax to one end of the loop antenna , Connect the center of the 75 ohm coax to the other end of the loop antenna. The length of the 75 ohm coax is most important. It will be used as a Q section.
To determine the length to use, Use this formula "Length in feet = 246 x VF / Freq in Mhz" VF = the Velocity Factor of the coax. So multiply 246 by the Velocity Factor of the coax , Then divide by the frequency .

If you use RG59 or RG11 with a Velocity Factor of 0.66 , For the 75 meter band the Piece of 75 ohm coax should be about 42 feet long , It doesn't need to be exact . RG59 and RG11 coax usually have a Velocity Factor of 0.66 , Foam dielectric coax such as RG6 might have a Velocity Factor of 0.81 or more.

Put a PL259 coax connector on the unused end of the 75 ohm coax, Screw a PL258 double female coax connector onto this PL259 coax connector. Then connect 50 ohm coax to the other side of the PL258 double female coax connector, Use any length 50 ohm coax needed to reach your Transceiver.

I use the built in tuner on my FT-920 or a MFJ-989C when using a linear amplifier to cover all bands from 6 thru 75 meters with this setup.

Hello Jim,

I've been experimenting with HF radio and antennas since the early 1970s. One thing I've learned is if you cannot hear a station, you cannot expect to communicate with it either (except by relying on relays from other stations). With this basic truism in mind, it is always best to go for an antenna that gives you excellent reception, a low angle of radiation, good efficiency, and a good transmitter match.

Concerning receiving antennas, for most HF reception we are looking for fractions of a microvolt receive signal, and anything that can reduce local electric field noise problems is a big advantage.

Balanced antennas feeding balanced lines and inductive coupling networks will always have an advantage in the reduction of local E field noise compared to any system using an unbalanced connection at the antenna. And a loop antenna, being much smaller because it is a single turn coil vs. a linear run, will always have less variation in the E field interference across its dimension vs. what is to be found from one end to the other on a dipole antenna. Basically, the E field consistently rises and falls in potential across the entire loop. This is a common mode effect that can be prevented from being coupled to your receiver input by using ladder line and an inductively coupled matching network. This simple principle is used in telephone systems to reduce crosstalk and 60 Hz hum.

Using plastic coated antenna wire in conjuction with 100k ohm resistors from each side of the balanced ladder line antenna feed to ground reduces precipitation static.

There are a few commercial HF loop antennas, with one being manufactured in England being very impressive in performance for 20 - 15 - 10M limited space installations. The old American made Isotron is another one.

I do not see any theoretical difference in loop transmitting ability with balanced vs. unbalanced line (coax), as long as the unbalanced line impedance is close to that of the loop. If it is not, then unbalanced line dialectic losses become considerable with high VSWR ratios. This is not as much of a problem with air dialectic lines such as ladder line.

I used my same home made inductively coupled antenna matcher in the early 1970s with a 75M doubled extended Zepp (.625 wave on each antenna half), homemade 600 ohm ladder line, a Johnson Desk KW and a Heathkit transceiver as Badger 205 in WI Civil Air Patrol. I could

consistantly "hear" our 5 W backpack land rescue team com sets across the state on missions and they could "hear" me. Because of my "ears" I eventually was nominated state net control. My secret was reducing local electric noise reception with my balanced antenna system and inductive coupled tuner.

I had a chance today to visit a local ham buddy and listen to his 20M reception of the 14.300 Mhz Maritime Mobile net off of his five element 20 - 15 - 10 M beam up at 45 ft. I did this right after listening to the same net on my own station. He had both a new Ten-Tec Jupiter and a new Icom 746 PRO. We switched back and forth between the two radios. His antenna VSWR was less than 1.2:1. His antenna was aimed toward the mobile stations. His local 13.6 KV powerline was about 250 ft. away. His "ears" were weaker (background powerline "sizzle" masking weak mobile stations) than my $15.00 homemade 40M loop 75 ft. from a 13.6 KV powerline feeding a boat anchor FT101B that has been stored in a box and put through multiple moves over the past 15 years without re-alignment. His noise blankers and variable bandwidth filters did not bring the weak stations out of the noise. This confirms that for reception a station is only as good as its antenna system design.

73 Leland NC9K

You wrote:

Hi Leland:

I found your comments very interesting, especially the effect of keeping a 'balanced' antenna such as the loop completely balanced. I do not know if there is a significant difference in performance from the transmitting point of view but I agree there is a significant difference from the receiving point of view. I do not have experience with a large horizontal loop eg full wavelength on 80 M for example, but I have used a full wave vertical loop on 20M, eg a quad and also small, 1/10 wavelength receiving loops.

In the first case, the 20M 1 wavelength loop, (quad) antenna, I have used coax feed to an unbalanced tuner, balanced feed (300 feed line) to an air core balun and then to a unbalanced tuner, the same system with a ferrite balun, and finally a balanced feed (300 ohm) to an inductively coupled balanced tuner. In all cases I was able to achieve satisfactory stable power transmission. However, on reception only the last arrangement (balanced loop, to balanced feed line, to inductively coupled balanced tuner) managed to reduce the local EMI. Every time I introduced coaxial cable I also significantly increased the noise from EMI ! Now that is contrary to what everyone tells you !

My experience with small 1/10 wave length tuned loops is for reception only. I tried a lot of different small antennas for SW broadcast reception in a rather noisy and space limited environment

(apartment block balcony), and soon concluded that the loop was the best bet. I started out with tuned loops made from coaxial cable and soon found tuning limitations due to the inherent capacity of the coaxial feed line. This limitation dictated that the antenna tuner needed to be close to the loop. I then experimented with using a simple wire loop fed with 300 ohm line to a balun/antenna tuner. This provided a quantum leap in performance and allowed the tuner/receiver to be located together in a convenient location. However, just by accident I replaced the balun/tuner arrangement with my old inductively coupled balanced antenna tuner and was impressed with the additional noise reduction and improved loop null.

My conclusion from this experience is similar to yours:

- noise reduction of a balanced antenna is due primarily to the fact it is balanced and has less to due with orientation.

- feeding the antenna has 2 major factors ..... impedance match for transmission, and maintenance of balance for reception.

- coax feed is not a 'no brainer'!

- the ideal situation is a balanced, low loss, feedline fed directly to an inductively coupled balanced antenna tuner (commercial units are rare).

- if you use an unbalanced antenna tuner the kind of device used to convert 'balanced' to 'unbalnced' eg "balun" is important from the reception perspective. For reception purposes I find RF transformers wound on ferrite or powdered iron cores with complete isolation from ground on the antenna side works just fine.

Now how could it be more simple than running 300 ohm feed line directly from the antenna to the tuner, with NO connection to ground! Use an ohm meter to check. I know we are not dealing with DC but RF .... however, it will affect antenna balance. Such an arrangement will handle a standard 100 W transmitter with good electrical and mechanical efficiency.

Hi Leland:

Yes, I agree .... years ago I used to be a real DX hound; I ran a 100 w AM transmitter and a HQ-129 receiver. The best antenna system I ever used (on 20M) was a cubical quad (home brew using bamboo) which was only up 30' on TV mast pipes. I fed it with 300 TV twin lead to an inductive antenna tuner. My technique was to listen at odd hours for very weak DX stations and was usually successful contacting them as I had no competition. I almost always avoided pileups during prime time hi. The key to the technique is good reception and a basic knowledge of propagation.

I have found that dipole type antennae are most often not balanced. If you place an RF amp meter in each side of the open wire feed line you often will see that the currents are not equal. The first time I saw this I thought that the meters were not accurate. I swapped them and saw the same imbalance! I can only assume that the electromagnetic environment was not the same each side of the dipole.

It's interesting you mention telephone line. I have used outside balanced telephone wire for feed line in some situations. It is extremely strong and impervious to weather. I don't know what the impedance is, but it must be in the 100 ohm bracket.

>Using plastic coated antenna wire in conjuction with 100k ohm
>resistors from each side of the balanced ladder line antenna feed to

I worked at a station out on the prairies years ago and we had balanced feed line coming into the radio room from an outside antenna .... I believe it was a rombic antenna ... . Where the feedline came through the wall on feed thru insulators we had spark gaps to ground just outside. I remember that when the wind came up the dust in the air would cause regular snapping across the spark gaps. The noise made reception all but impossible. The solution was what you suggest, small high value resistors by passing the spark gaps!

I have used a double extended Zepp (75M) for years out at my farm. I don't have commercial power there but operate from a battery with a solar panel. I use an old TenTec qrp Argonaut which puts out about 2.5 watts on SSB. I rag chew with stations and manage to keep up with everyone running 100 watts. In addition I often relay for others who can't "hear" the other hi! Of course being out at the farm I not only have the advantage of a great antenna .... but no local noise hi. The only noise I ever hear out there is some electrical storm off in the distance!

It was very nice hearing from you and your refreshing point of view .... what I usually see vis-a-vis antenna performance is SWR ..... If you are only going to communicate with those S9 stations then I guess that is okay. However if you are going to hear and work the weak stations you have to look beyond the SWR performance and you don't necessarily have to have an expensive beam antenna.

From: David Shrum
Topic: 383 Message: 467

Well I will not tell you what to do, but checking the archives, this is the 3rd post to this group with almost the identical message; according to the archive someone with the Yahoo ID of "inu6080" made those posts on the dates of, Wed 2/18/2004, Fri 4/23/2004, Sat Apr 24, 2004. So the only thing I would like to know is why do we need to hear about this group for the third time. If it has something to do with making antennas that is one thing, but I do have my doubts. I personally have nothing CB, but this group IS about making antennas, specifically loop antennas. If you are willing to talk about that general subject, I am more than willing to listen to your ideas, other wise I will add you to my ignore list for this group.

468. Twin roller inductors vs. coupling transformer

Yahoo group: SkyWires
Date: 2004-04-26 00:57:55 UTC
From: nc9k
Topic: 468 Message: 468

Hello Greg,

Your email inspired me to scan the W6SAI antenna coupler projects from his 1970 edition of the Radio Handbook. He also discusses harmonic reduction techniques. The files are posted in the Skywire Group at: http://groups.yahoo.com/group/SkyWires/files/

I also took a photo of the actual balanced coupler I built in 1974 and still use, now with a 40M loop, as well as a telephoto shot of my 450 ohm ladder line connection to the 40M loop. (Please excuse the look of the coupler, I was 14 at the time and on a tight budget. It handled a full tilt Johnson KW Desk without complaint on net control duty on a daily basis.)

On to the comparison of inductive coupling vs. twin roller inductors: The twin roller inductors would be useful for correcting the impedance of each half of a dipole, or say each feed connection to a loop. This matching could be necessary if there was enough of an impedance difference between the feed points. To be truly effective the roller inductors should be mounted at the antenna feedpoints and adjusted there (in conjuntion with any capacitive matching required) to provide a non-reactive load to the feed ladder line or coax. This is how it is done in military and commercial work. This would not be practical for most of us on a budget too small to afford remote tuning devices.

The second best place (and most practical) to locate the matching network would be in the station near the transceiver. This location then presumes a near symetrical antenna impedance load on the feed system. The antenna coupler then "tunes" the entire feedline and antenna as one unit. There will be a large impedance mismatch between the antenna and feed system at certain frequencies. This is not much of a problem with a balanced feedline, but becomes a potential source of major problems with coaxial feed connected directly to the antenna (voltage breakdown of the dialectic or current overheating of the inner conductor).

The question then becomes roller inductor vs. coupling transformer? If the load your antenna presents to a balanced feedline is uneven, you will get radiation from the feedline during transmit (and also noise pickup on it during receive). You could use the dual roller inductors to try to somewhat reduce the unbalanced condition on the feedline. But it is an expensive approach to a problem that should be addressed in the first place with the antenna itself. A single roller inductor based tuner would be the best approach for feeding an end fed single wire antenna or the center conductor of coax feeding

some type of dipole antenna.

If your antenna is nearly balanced electrically, then the inductive coupling transformer approach allows for lower overall project cost, dc isolation via winding separation, much faster bandchanging - retuning, and an overall comparable power transfer efficiency compared to twin roller inductors. I hope this helps.

Topic: 468 Message: 469

HI Leland and the Group,

I just went to the FILE section here on Skywires and downloaded the pics of the coupling system you posted.. I would encourage anyone here to do the same..

I think there is much I will learn from reading the articles in full. from what I can see just glancing at them, there is some good stuff here.

I also want to take a minute to thank all those who have been so helpful in assisting me getting my wire working..
I found that with my MFJ tuner I had to go to each band and find my "OWN SETTINGS" not the ones that come with the book.. I think the instruction manual sort of assumes you have a balanced dipole and some sort of simple antenna, not a "500 ft loop"!!!! LOL
I found some settings to be close the book suggestions.. but many were far from them.
also I notices that I am struggling to get a match on the top of 10 meters and on the top of 75meter bands. anyone else have this issue arising? if so how are you working with it and so on..
IM getting at best a very shallow notch . thin bandwidth coverage "per tune" and at very best about 2:1 swr.. where on the rest of the band I get nice flat matches much of the time.

again thanks to the group.

73s from south west Michigan USA. Kc8hps Bryan

Hi Leland:

Very interesting comments again. My present balanced antenna tuner uses a coupled RF transformer. EG. I have a parallel resonant circuit made of old airdux inductor and a 250 pfd transmitting capacitor. One end grounded and the other end fed to my transmitter via another large 500 pfd transmitting capacitor. I have a larger diameter airdux coil that slips over the first inductor and it feeds the balanced line. I believe this is the Z-match circuit.

It works very well. however, I recall telling you that balanced antennae such as the doublet most often don't have equal antenna currents in the balanced feed line. I speculated that the reason was probably because the two sides of the doublet probably exist in different electromagnetic environments ... eg one side closer to metal objects or over different ground characteristics etc.

You mentioned using a double roller system for a balanced feed line system. What comes to my mind when I think of a double roller/inductor tuner is to place one in each side of the balanced feed line, place a capacitor between them to form a double L filter. The trick is feeding the other end of the inductors with the transmitter. Here is where the balun comes in ..... a much more appropriate place eg low impedance point. I saw the advantage of the double inductor system as simply allowing the use of the balun at the low impedance point (using them in hi impedance hi power situations is asking for trouble). I have tried this with matching airdux coils and taps and soon gave up since the mechanics got a little complicated. I thought of using roller inductors with some mechanical means of coupling them so they could be rotated in unison.

I went over to the Z-match circuit. However, I never thought of using them to balance the feedline as well as match the system. I wonder if you have had the opportunity to try and balance the feedline system to a doublet type system.

I have used a loop antenna in the past and fed that antenna with a balanced line and Zmatch tuner. I never had the opportunity to check the feedline balance. I would assume that loop type antennae would be naturally balanced unless it was extremely large and would not be subject to effects of the surroundings as is the doublet.

Hello Jim,

You have a nice Z-match setup there. Usually the primary of a transformer type coupling circuit is series resonated. What type of variable capacitor in your Z-match "tunes" the output of the transformer coupled to the balanced line feeding the transmission line?

The only reason a dipole type antenna would present uneven loads to the balanced feedline is if there is some type of electrical discontinuity making one half of the dipole different from the other half. In this type of situation a person could use a "tuning" capacitor on the secondary of the coupling transformer that is not "center tapped" to ground. This would "float" the entire coupler secondary - antenna system and allow for a better chance of impedance correction of the entire system without introducing an unbalance due to a ground current being injected into the equation. You could use a vaccuum variable capacitor (best choice, but expensive and slow to tune), or, if you are creative, you could "float" the entire ganged dual tuning capacitor attached to the coupler transformer's secondary from ground. You would have to be careful to use high voltage RF isolation techniques for both the frame of the variable capacitor and the shaft connection to its tuning knob! I've seen this done sucessfully using bakelite.

Years ago I placed an RF ampmeter into each half of the coupler feeding the 600 ohm ladderline connected to my 75M double extended Zepp. The meter read the same current on each leg with carrier applied. Therefore, things appeared to be balanced at that point.

One has to watch out for imbalances introduced by toroidial or coaxial transformers used in antenna balun systems. Some circuit configurations such as using the toroid to introduce inductance effecting a "transformer" effect for the transmission line (twisted wire or coax) wound around it can result in uneven impedances and currents - phasing in the "output" of the balun. I conducted extensive network analyzer testing of this effect while a senior engineer at Northrop Corp. What you observed as an "uneven" condition in your dipole could have actually been an electrical impedance - phasing problem being caused by the balun feeding it.

A loop antenna can present uneven loads at its feedpoint due to discontinuities on the loop that are closer to one end of it than the other. Again, the best way to deal with this type of problem would be a coupler with the "floating" secondary capacitor system I described above.

Thanks for the interesting questions.

Attachments: 1 described; binary payloads are missing from this source WARC

Hi skywire fans,

Here is the schematic of my horizontal loop using an Icom AH-4 automatic antenna tuner:

Is anyone out there using an AH-4 in their horizontal loop? I am getting good results on 6M and general
shortwave listening. Yes, the tuner(coupler) is outside on the mast up about 30 feet and the loop is
directly connected to the tuner. SWR is always less than 1.5 to 1 after the TUNE button is pressed
on the radio. The only limitation is that the power must be less than 100 watts(Icom tuner). With a larger
loop the AH-4 can tune down to 160M. My next modification is to make the loop square and larger.

Good listening to all.

Great info TOM

This is exactly what I've been looking for. I have Icom 706 and the AH4. I was not sure if using it (AH4) with loop you would connect both ends of the loop to the tuner or the ground of tuner to ground. I was going to ask on the list but now I know. As soon as it stops raining here I'll give it a try. Thanks again.

Hi Drunk and the Skywire group,
>Drunk asked, in reference to the AH-4 tuner:

>Any L and C values?

My schematic is a simplified one, just showing the tuner and RF paths.
The inductors are in the right form, but the capacitors in the AH-4 had to be built up from parallel caps for more capacitance and in some cases capacitors were built up from series networks to withstand the high voltages at 100 watts.

Here is what I gathered from the schematic and parts list:

L1=50uH L1=.0012uF
L2=60uH L2=500pF
L3=70uH L3=300pF
L4=80uH L4=150pF
L5=90uH L5=75pF
L6=100uH L6=38pF
L7=110uH L7=19pF
L8=120uH L8=9pF
L9=130uH L9=14pF
L10=100pF

The inductor values may be incorrect as they were not given in the schematic, but referred to in the parts list as L1=6110002750, L2=6110002760, L3=6110002770, etc. I would highly recommend buying a copy of the AH-4 Service Manual for a full schematic and theory. My part numbering is a little different than Icom's for simplicity sake.

It may be possible to increase the size of the L's and C's for more power handling. The circuit can provide 1,040,000 LC combinations to achieve the lowest SWR, according to Icom.

Have fun with loops.

Hi Drunk.

I goofed again, I meant C1-C10 values for the capacitors.

Tom

Subject: Re: [SkyWires] AH-4 loop.....Correction, 1 more switched capacitor in the schematic

Hi Drunk and the Skywire group,
>Drunk asked, in reference to the AH-4 tuner:

>Any L and C values?

My schematic is a simplified one, just showing the tuner and RF paths.
The inductors are in the right form, but the capacitors in the AH-4 had to be built up from parallel caps for more capacitance and in some cases capacitors were built up from series networks to withstand the high voltages at 100 watts.

Here is what I gathered from the schematic and parts list:

L1=50uH C1=.0012uF
L2=60uH C2=500pF
L3=70uH C3=300pF
L4=80uH C4=150pF
L5=90uH C5=75pF
L6=100uH C6=38pF
L7=110uH C7=19pF
L8=120uH C8=9pF
L9=130uH C9=14pF
C10=100pF

The inductor values may be incorrect as they were not given in the schematic, but referred to in the parts list as L1=6110002750, L2=6110002760, L3=6110002770, etc. I would highly recommend buying a copy of the AH-4 Service Manual for a full schematic and theory. My part numbering is a little different than Icom's for simplicity sake.

It may be possible to increase the size of the L's and C's for more power handling. The circuit can provide 1,040,000 LC combinations to achieve the lowest SWR, according to Icom.

Have fun with loops.

I know almost nothing about AM radio reception and while I am not fixed on becoming a BCB DXer I would like to get enhanced AM radio reception if possible. Using a variety of shortwave antennas ranging from dipoles with traps to long wires I get very little AM reception, day or night, on any of my various Hallicrafters boat anchors or modern SWL rigs. I have concluded that probably some, to maybe most of the issue, is related to my geographic situation with nearby mountains, but I would like to see if I can mitigate that and get some kind of reception. Would my best bet be to try and work with one of my old Hallicrafters or should I concentrate on one of the modern SWL rigs. How about antenna?? I have won one of Radio Shack's discontinued loop antennas and it should be her this week. Any other thoughts on an antenna. I don't want to spend a fortune on this, the budget is tentatively $100-$200. Shortwave reception is certainly impacted but I am still hearing plenty of stations, now I would like to hear a few AM ones.

Good points. I am refering to the traditional American (Medium?) Wave band of 540 KCs to 1,600 KCs (Now expanded just a bit??) My longest wire right now is around 85-90 feet. Conceivably could get it to 150'. Getting it above the terrain N, S, and E of me is not remotely feasable. The Pacific Ocean in the form of Puget Sound is 50 miles West of me. At this point my unscientific belief, based on very casual observation would seem to sugest that the better boat anchors, in my case a Hallicrafters SX-71 and a Hallicrafters SX-42 are pretty competive when it comes to sensativeity on the shortwave bands with some the moderate to higher end SWL orientated receivers.

Dan,
Thanks, I thought I saw an ad in either Monitoring Times or
Pop Com last night for an AM antenna from Crane. Crane looks better than
Universal in this area.

Hi Bill:

Here is how I managed to improve AM reception with an external antenna. By the way .... the colloquial term for MW here in North America is "AM". I have 8 two band receivers in the house including 2 Hi-Fi models that refer to the 540-1600 Khz band as "AM" and the the 88-108 Mhz band as "FM". Even my single band "TRF Long Range", and RCA "Globe Trotter" 1930's vintage receiver refer to 540 - 1500 Khz as the AM band. So go figure.

I have a little cabin out in the woods and like to receive AM stations from Northern Wisconsin and Minnesota during the day (200-400 miles away). I have an 85' doublet fed with open wire line that I use for ham radio. The receiver I use for local broadcast out there is a simple battery operated AM/FM radio from RadioShack. On its own it is not a bad AM receiver as it has a decent size ferrite rod antenna, but no RF amplifier or provision for an external antenna.

My first attempt at improving AM reception was to open the receiver and put a 2 turn link around the far end of the loop stick and bring the ends out through a little hole I drilled in the plastic case. Using a jumper wire with alligator clips I clipped one wire from the receiver to the antenna feedline using it as a long wire. Signals definitely came up a bit. Next

I place some wire on the ground as a kind of ground/counter poise and connected this to the other wire from the receiver link. Signals improved again but with side effects.

At some frequencies it worked perfectly. At other places on the dial I got oscillations, while at others I actually received shortwave broadcasts !!! It seemed to be over loaded to some degree. It was clear to me it needed some kind of an improved front end.

My second attempt at using an external antenna came later as a result of building a small tuned loop 15'x15'. I built the loop with hook-up wire and an old 365 pfd tuning capacitor. I then tuned the loop to a desired station and coupled it to the receiver by just orienting them for best reception. This system was better than my first attempt using the long wire and link to the ferrite rod.

Then, out of curiosity I connected the long wire with a test lead to one side of the loop !!!!! the signals just jumped up to the loudest I have ever heard them. I readjusted the loop/receiver orientation again for best reception. Next I dug out my ground/ground plane wire and connected it to the other side of the tuned loop and the signals jumped up again another quantum leap. With this arrangement it seems the tuned loop in conjunction with the antenna and ground acts like an antenna tuner. The coupling is easily accomplished by orienting the relationship between the receiver and the tuned loop. This arrangement allows me solid reliable reception of many AM stations in the Wisconsin/Minnesota area during the day .... at least a couple of dozen using my old plain Jane RadioShack AM/FM receiver.

If you use a receiver without an internal ferrite rod antenna which has an external antenna connector it will be just a bit more complicated. The method I use is to connect the antenna to such a receiver is to use a coupling loop. So you have a tuned loop antenna, you have the long wire connected to one side and the ground to the other. To couple this to your receiver you need a second untuned coupling loop. The kind of coupling loop I use (for my hi-fi receiver) is 3 turns of hookup wire on a light 8" dia plastic form (looks like one of those embroidery hoops). The loop is connected to about 3' of twisted pair wires with spade lugs on the end. I connect the spade lugs to the antenna input screws on my Hi-Fi receiver. I select the frequency on the receiver, bring the coupling loop close to the tuned loop with the external long wire and ground connected to it, and tune the loop for best reception. The system works like a charm and is much much better than trying to connect the long wire and ground directly to the receiver input.

483. One Metre AM/MW Loop Antenna [Was: An AM antenna]

Yahoo group: SkyWires
Date: 2004-05-03 23:27:08 UTC
From: R H F
Topic: 478 Message: 483

BK,

Take a Look at the AUSTRALIAN ONE METER SQUARE Loop Antenna
for a AM/MW Loop Antenna that will "Improve" 'weak' AM/MW
Reception in 'poor' AM/MW Signal Locations/Areas.

A larger Loop Antenna has a greater Signal Capture Area
and usually this results in a higher Signal Output.

* The Australian 1 Metre Loop from Hard-Core-DX.Com
- by Werner Funkenhauser
http://www.hard-core-dx.com/nordicdx/antenna/loop/1mloop.html

* Bigger Image of the "Australian 1 Metre Loop"
http://www.hard-core-dx.com/nordicdx/antenna/loop/rnloop1.gif

* The One Meter (3-4Ft) Loop Antennas all perform really
good, but they are big and need a lot of space to position
them and operate them.

From: Bryan Burrma
Topic: 486 Message: 486

HI GROUP,

since we are on the subject of "AM" radio.. which
stands for Amplitude Modulation btw.

Here In Kalamazoo Michigan "south west Michigan" we
have an AM station 590KHZ callsign WKZO

you all may want to see if you can here it. it was the
very first PHASED VERTICAL station put on the air in
the USA. 4 towers feed in and out of phase in order
to get a directive pattern for our city at night!

I would be Curious if JIM in Thunder Bay could hear
it..
it comes in real well on my skywire of 500ft, yet
again.. im only 3 miles from the transmitter site. LOL

tell me what you hear..

487. Trying to match to coax...

Yahoo group: SkyWires
Date: 2004-05-05 17:16:01 UTC
From: jdh7521
Topic: 487 Message: 487

For no good reason other than "because I could", I've restrung my 300 +/- foot random wire antenna into a 100 +/- foot loop (triangle strung horizontally).

Although the antenna is fairly level, it's over sloping ground, from about 10' at the feed-point to a bit over 30 feet at one of the other corners.

So, I have about 100 feet of #14 stranded-insulated copper in a flat-horizontal configuration fed with 75ohm coax. At the feedpoint, I have a 9:1 matching xformer. I have both sides of the antenna connected to both sides of the primary and both sides of the coax connected to both sides of the secondary. The coax goes to a ground block before entering the house.

Now, right now, it appears to be performing fine. Not as much signal as the prior random-wire, but the noise level appears to have been cut noticeably.

I have no way of determining the actual impedance of the antenna, so I'm not sure 9:1 is the best match. Also, the way I've attached the antenna to the xformer removes the direct path to DC Ground.

Is there a rule of thumb for impedance with a loop like this and any ideas on how to take into account the terrain sloping away from the antenna?

Should I connect the primary and secondary to ground off the shield?

I'm asking because I glued the xformer case (it's PVC fittings) and before I start cutting it open, I'd like to have some idea of what (if anything) I might want to try.

Thanks all!

Have you seen my loop using an Icom AH-4 automatic antenna tuner?
It does a very good job of matching a horizontal wire loop to a coax without any strange transformers or baluns:

The tuner would be happier with 50 ohm coax, but 75 ohm coax would probably be OK.
The AH-4 will work with ANY transceiver with a simple mod circuit, but favors Icom transceivers. On receive it can boost the signal
1 or 2 S units. For receiving only, I would use a manual antenna tuner unless you only listen to one frequency.

On transmit it can match the loop to the coax with an SWR of 1.5 to 1 or less. With my 126 foot loop,
the frequency range is 3 MHz to 50 MHz. With bigger loops it would go as low as the normal broadcast band. Is anyone running an AH-4 or ANY variable antenna tuner??????????????????

Good listening out there.

Hi Bryan:

Interesting about your station on 590 Khz., WKZO. I will have to give it a listen. My "AM" listening post out at the farm is soon coming to an end. I am selling the property this spring .... with mixed feelings. However it provides new challenges. I plan some new wire antennas here in town. I have a fairly good size garden in town and I am planning to put in a double terminated loop antenna for MW. This is the antenna invented by K9AY I believe. From what I have read it is supposed to outperform most long wire antennas. My summer project includes building a small Ham shack out in the garden as well as some new antennas.

Listening for WKZO will be a good test because the only AM station in Thunder Bay happens to be CKPR on 580 Khz !!! It only runs about 5000 watts but It booms in here .... but then it is only about 3 miles away Hi. If I hear WKZO I'll be sure to let you know ... I have a note on my bulletin board !!

HI Tom,

you had asked if others of us use tuners... and YES I use an MFJ 934 with artificial ground capabilities.. this comes in real handy when you want to run a long wire thrown up in a tree while camping and have no room to pack extended ground rods and other gear.

I used this tuner with my FT 840 yeasu on 20 meters last summer from Mackinaw Michigan near the Mackinaw Bridge and talked to cape hatteras Islands near the carolinas on ten watts. and "NO GROUND".

tuners do help out alot.. I know the www.mjfenterprises.com site has download of their manuals for tuners.. maybe they would shed some light on what your seeking.

to the guy with the 9:1 balun.. yes I think 50 ohm coax might help a bit..

ive heard tell while talking to guys about copper loops that the loop resistance if "COPPER" not stainless steel is about 2 ohms.. copper loops should produce a very low resistance factor. conversely my stainless steel 500ft loop witn thin vinyl coating has a resistance of about 158 ohms. hope that helps.

Bryan Kc8hps south west michigan usa.

Hi Tom,

The transformer is a simple toroid design and is quite
easy to construct -plus- I probably have less than $10 in it. Also,
I'm only using the antenna for SWL so I don't have to take TX into
consideration.

So it should be resonant at roughly 3.3,6.6,13.2,26.4 mhz
signals should peak around those frequencies.
signal

A loop at it its fundamental will have an impedance of something
like 100 ohms rising thousands of ohms impedance. Your 9:1 and
75 ohm coax will give you an impedance around 700 ohms so the
SWR would be something like 700/100 = 7:1 at a low impedance
point and something like 5000/700 = 7.14 :1 at a high impedance
point. Using the 9:1 balun keeps the impedance mismatch down
to something relatively close to what your receiver likes.

> Is there a rule of thumb for impedance with a loop like this and
any
> ideas on how to take into account the terrain sloping away from the

The lower the average height of your antenna, the lower its
impedance.

> Should I connect the primary and secondary to ground off the shield?
>

I would think you would want the primary and secondary isolated...
Dont know how you wired your balun.

I wonder what the input impedance is of your receiver?

If it is a high impedance like direct into a FET then maybe
that explains why you have a drop in signal strength when
you connect the loop ends since the loop might have
a lower impedance than an end fed wire.

You might try building a little antenna tuner out
of a wound toroid with multiple taps and an old tuning cap
from a transistor radio.

Check this out:
http://www.qsl.net/wb3gck/tuner.htm

The cool thing with an L network is that you can turn it around
backwards to match low impedances instead of high impedances.

I built one and use it with my qrp rig.
I bet it would help with your SWL signal level on receive.

The ends of the loop are connected to both sides of the primary -
the shield and center conductor of the coax are connected to either
side of the secondary. I use opposite side windings. The shield hits
a ground-block on the way to the receiver.

I was wondering if I should provide a path to ground for one side of
the loop. I have a static bleeder on the receiver end, but this is
the first antenna that I've strung that did not have a direct path
to ground at the feed-point. Since I've always had end-fed randoms,
I've consistently connected one side of the transformer primary to
ground. I'm presuming that with a loop, it sort of acts as it's own
counter-poise? I'm just guessing here...

> I wonder what the input impedance is of your receiver?

Icom PCR1000 - 50 Ohms, I believe?

>

I've been itching to build one, but I lack the capacitor. As soon as
I can scare one up, I intend to - Thanks for the link to the design.

Thanks again,
-=JD=-

> counter-poise?

yes. A loop (like a dipole) has its own counterpoise.

I have heard of guys DC grounding thier loops to earth
through high value chokes for electrostatic protection
but I have no experience with this.

I have fed loops directly with coax from the unbalanced output
of a rig so that means that the loop in this case is at DC ground
since the shield of the rig (which is attached to one end of
the loop) is at DC ground.

502. Optimum length for 160m full wave loop.

Yahoo group: SkyWires
Date: 2004-05-10 20:16:09 UTC
From: Bill Ort
Topic: 502 Message: 502

I am planning 5 masts for an irregular pentagon to be fed with ladder line to a Johnson Matchbox (275W). The available perimeter is somewhere between <520 - >560++ feet (there is a bit of adjustment available on the exact placement of one of the masts, the other masts are fixed. I want to use this antenna for multi-band use and am not sure yet exactly what precise frequencies I might be on. Since I will hoist up each point with a pulley and dacron rope the excess between the total wire length and the actual perimeter (call it "D") will allow a certain distance away from the metal masts which I assume is desirable. My question is: what would be a good precise antenna length to shoot for given the intended multi-band use AND taking into consideration that I can utilize "D" for spacing the antenna wire away from the metal masts a few feet at each facet?

(1005/3.8)x2 = 529 feet, ok, but is (are) there other length(s) that might have some obscure magical mystery properties I may be overlooking. Obviously I am more interested in 75-80m band than 160m per se.

I though I heard somewhere that calculating for the "lower" part of the 80m band had some advantage, but I cannot find that reference. Also, once I determine what part of 75-80m to calculate for, do I just double it to be in the ballpark of my available perimeter?

From: kl7r
Topic: 502 Message: 504

If you are going to use a tunner and ladder line, dont worry
about the length. The bigger the better.

But...

1004/1.8 = 558 feet
1004/3.8 = 264 * 2 = 528 feet
1004/7 = 144 * 4 = 574 feet
1004/14.0 = 72 feet * 8 = 576 feet

I might try for 576 feet but I know of guys with 500 and 800
footers and they work great even though they are not perfect
lengths.

I did notice when I cut my 80 meter loop for 20 meters
(1004/14.060) * 4 = 285 feet that resonance was non linear
by band. What I mean is that the loop (cut for resonance on
14.060) resonated something like this:

3.2 6.9 14.1 21.5 and 29.5 mHz.

(my loop is at about 35 feet average height)

Go for big and high.
Experiment with shapes with MMANA or an other antenna modelling tool.
Think rhombic on the higher bands.

Mine is 1080' Resonant at 1.86 and 0.93 I guess really, but fed with 450ohm ladder line it tunes great every where that I can go with my old Kenwood 440, and it works well for me, I dont even use my beam much any more.

506. RE: [SkyWires] Re: Optimum length for 160m full wave loop.

Yahoo group: SkyWires
Date: 2004-05-10 23:46:08 UTC
From: Mark Banks
Topic: 502 Message: 506

I ordered 600' of wire and couldn't see cutting it so I just put up the whole 600' fed with 450 ohm ladder line. Tunes all bands I have tried. It's resonant at some goofy freq's but who cares if your using a tuner...

BTW, when other stations talk about noise and not being able to hear weak stations I seem to do better than most. These closed loops listen very well...

de,

Mark, W6SPT

Subject: [SkyWires] Re: Optimum length for 160m full wave loop.

If you are going to use a tunner and ladder line, dont worry about the length. The bigger the better.

But...

1004/1.8 = 558 feet
1004/3.8 = 264 * 2 = 528 feet
1004/7 = 144 * 4 = 574 feet
1004/14.0 = 72 feet * 8 = 576 feet

I might try for 576 feet but I know of guys with 500 and 800 footers and they work great even though they are not perfect lengths.

I did notice when I cut my 80 meter loop for 20 meters (1004/14.060) * 4 = 285 feet that resonance was non linear by band. What I mean is that the loop (cut for resonance on 14.060) resonated something like this:

3.2 6.9 14.1 21.5 and 29.5 mHz.

(my loop is at about 35 feet average height)

Go for big and high.
Experiment with shapes with MMANA or an other antenna modelling tool.
Think rhombic on the higher bands.

And you've hit upon one of the loop's strengths... the loop is much more (though not totally) immune to power line interference. Compared to a dipole, it's the winner, hands down.

Congrats on selecting the very best right antenna for your backyard!

73, and wishing you success,

520. LOOP vs Powerline

Yahoo group: SkyWires
Date: 2004-05-17 02:47:21 UTC
From: Bryan
Topic: 520 Message: 520

HI to the Group,

I have a 500 +/- ft loop two sides of it are paralell to
power/phone/cable lines etc.

they range from 30 to 40 ft away. and I have little to NO NOISE level
from them. I have found the loop to be a very good listener. the
noise level is low and I hear stations that the Dipole just can not
hear.

hope that helps. a LOOP is a GOOD choice for almost anyone.

Here are the best ways to actively do something about spam, report to
Federal Trade Commission;
uce@...
use Spamcop service which is free and reports them to the originating isp;
http://www.spamcop.net/anonsignup.shtml

be sure to forward the spam with full headers, Ron, ag4lh.

522. Hoist-rope to Antenna-wire junction?

Yahoo group: SkyWires
Date: 2004-05-19 15:03:08 UTC
From: Mike Valentine
Topic: 522 Message: 522

Hi All,

I've been a full-wave loop user for about a dozen years.

Now, I'm expanding from a 270' loop to a 540' loop, and to cut down on the weight, I'll be using some small diameter (jacketed #18) copper-clad steel wire. The steel core should eliminate the dreaded stretching as well as provide the necessary strength (250#).

I occurred to me to ask what other people do when joining the hoisting rope to the antenna wire. I've read of plastic pulleys, but I worry about the antenna wire getting jammed between the pulley and the frame unless I use very large diameter wire.

The medium diameter wire I have up now uses 2"-long pieces of PVC tubing that have been slit length-wise and have two holes drilled adjacent to the slit. The wire can be slipped through the slit and then the support line can be fished through the two holes and then tied in one's favorite knot. This allows the support point to be adjusted during installation in a convenient manner and allows the stress on the antenna wire to be spread out a little bit.

What are others' favorite little tricks for attaching the rope to the wire on a SkyWireLoop?

Cheers,

Mike - W8MM

523. RE: [SkyWires] Hoist-rope to Antenna-wire junction?

Yahoo group: SkyWires

From: Mark Banks
Topic: 522 Message: 523

Mike,

I used common electric fence insulators and tied the dacron rope to the insulator. The rope then goes to a pulley attached at the top of my composite aluminum/pvc poles. (2" 32' long irragation pipe with 5' of schedule 80 x 1 1/2" at the top to minimize coupling to the aluminum). After I had hoisted each of the corners I was still able to drag the 600' of 14 gauge bare copper through the insulators to center up the 450 ohm feed line between two trees. Also, the semi flexible nature of the pvc allows the masts to bend in the wind without putting undo pressure on the wire or other components. Next move might include putting the 2" aluminum pipe inside some 3" I have in a sort of push up arrangement if I can figure out a decent guying arrangement...

524. Re: Hoist-rope to Antenna-wire junction?

Yahoo group: SkyWires
Date: 2004-05-20 15:42:21 UTC
From: nc9k
Topic: 522 Message: 524

Hello Mike,

I am using #12 AWG stranded plastic coated copper wire for my 40M loop. It is in a square configuration. The #12 wire is suspended at each corner via 36 inch long UV resistant bungee cords with metal hooks on each end. The antenna wire end of the bungee has its metal hook passing through the center of a plastic electric fence corner insulator to form a slip joint for the antenna wire. Also used is a piece of 14 AWG solid wire formed as a loop passing through the center of the insulator to "trap" the antenna wire so that it cannot jump out of the corner insulator groove.

The other end of each bungee is attached to UGV resistant rope and positioned over the crotch of a tree about 40ft. up. The rope is pulled down the tree far enough so that the bungee is what passes over the tree crotch, not the rope. Each rope is then tied off lower down the tree.

So far this arrangement has survived multiple severe thunderstorms with high winds without failing.

Hope this helps.

73's Leland NC9K

I use recoil rope for lawn mowers or chainsaws, and snowmobiles. It has been ok so far and you can get different sizess. I found the real small a little tough on the hands with the weight I have on this large loop.

Walter & the Group,
With this group currently having 255 members and hopefully growing, I would suggest that it not have 'A' moderator but several because as you stated your schedule sometimes gets busy and can't devote the time you want to, here is my suggestion, Walter don't give up this group a moderator, but add several say around 5 or so if you can get that many replies offering to help. That way the chances are someone would be around to moderate new members for their first few messages until it is determined that they are some one interested in this group instead of just spamming the group with junk and posting in-appropriate links as well.

I offer to help, but NOT by myself because of my job I could only do it most evening for a few hours, which would not be enough (I my opinion) to do this fine group justice. So that is my suggestion and case.

With this group currently having 255 members and hopefully growing, I would suggest that it not have 'A' moderator but several because as you stated your schedule sometimes gets busy and can't devote the time you want to, here is my suggestion, Walter don't give up this group a moderator, but add several say around 5 or so if you can get that many replies offering to help. That way the chances are someone would be around to moderate new members for their first few messages until it is determined that they are some one interested in this group instead of just spamming the group with junk and posting in-appropriate links as well.

I offer to help, but NOT by myself because of my job I could only do it most evening for a few hours, which would not be enough (I my opinion) to do this fine group justice. So that is my suggestion and case.

Subject: [SkyWires] Who wants to moderate this website?

I started this group last year but lately have been way too busy to check it.

This is the first time I've been on here since March or so. I apologize in that it seems spammers have been clogging it up, and I haven't been here to take care of it.

If anybody else would like to moderate this site, please nominate yourself, and every most everybody (including me agrees), then the site is yours.

Just reply to this message, and in two paragraphs or less, plead your case as to why you believe you would make a good moderator.

Thanks.
Walter

Hi,

I didn't want anyone to think I was going to delete the group or something. I was just letting everyone know that I haven't been as attentive as I should be and I was hoping someone else would like to step up to the plate.

It looks like we have at least 4 or 5 people who would like to c-moderate. Thats sounds great. Does anybody know if the yahoo software will allow more than one moderator at a time?

If so, I'll make the changes.

thanks.

Walter,
Yes, when I had a group I had several moderators (deleted the group from lack of activity), you can have as many as you like.

From: Robert
Topic: 522 Message: 536

My "trick" is those el-cheapo multi-colored clip-hooks you can get at Home Depot or Lowes for a buck or less. I just tie the rope to the clip and snap the wire on (open the hinge and pass the wire through the clip-hook. My loops all "float" in this fashion and I have not had one come down yet. FYI, I use 3/16 double braided dacron (black outside/white inside) rope. My supports are two telescoping masts with pulleys on top, and several treetops (just throw the rope over the tree,pull tight and tie off conveniently).

537. Re: Optimum length for 160m full wave loop

Yahoo group: SkyWires
Date: 2004-06-01 03:45:01 UTC
From: Robert
Topic: 537 Message: 537

Loop length does matter on the lower bands in particular. It is true that tuners compensate for non-reasonance, but while sometimes loops will "tune", they can be difficult to tune and have very narrow resulting bandwidth.

I experimented with the length for my loop and finally decided to build a relay-based version of W5DKP's "no-tuner" system. My version switches in an extra 2-64' of ladder line in any 2' increment using five 10A 4PDT relays. This allows my loop to be fed at current maximum point for each band/frequency. I have used this system for a few months now and it works great. I can tune the loop without my Johnson Matchbox on most frequencies, but still use the tuner to tweak SWR completely flat every time. My Icom 746Pro's SWR protection circuitry is pretty stingy. Even though in theory full power may be delivered to the antenna with some SWR, the protection circuitry will roll it back. Probably a good thing..... :-)

this style loop sounds interesting to me as well.. so
are you adding a lenght of ladderline to your FEEDline
or in the loop itself? if so does it hang down or is
it suspended at a right angle or coiled up? tell us
more..

From: cfsimm2004
Topic: 541 Message: 541

Can anyone suggest what are where I can look for pole or something to use for pole to erect a skywire? I have no trees on the property of any usful height, I can use a push up pole on my shack for a height of about 50 feet. Was looking at the local co-op and they can get telephone pole-like poles that are about 45 feet. The problem is after you rent an auger to dig the hole how do you set the 45' pole in the hole. Of course if I was rich I would just have a crane come and set them. I can get use of a large Back-hoe will this and a sling work to lift them to set them??? Thanks and any ideas would be great!! 73's PS the reason I did no mention more push up pole is the wife hates all the guy wires (The current push up poles-4 ea.) is why she is willing for me to put up 2 towers instead.

543. Variable Feedline System

Yahoo group: SkyWires
Date: 2004-06-03 16:22:53 UTC
From: Robert
Topic: 543 Message: 543

I am changing feedline length by adding in sections of 450 ohm line with relays. I can switch in 2, 4,8,16,or 32' with five switches/relays. This moves the current maximum point on the feedline for a given band/frequency. It also avoids the "bad length" problem that hams run into sometimes when they cut the feedline to specific length. The ARRL Antenna Book in the past at least had a chart that showed optimum feedline lengths and lengths to avoid for a given band.

The extra sections of ladder line come out of a plastic box with the relays inside mounted on my wooden patio cover. I do not recommend trying to roll up the extra line lengths, you need to find a place for them to hang or be supported. I use my patio cover for this.

I will be putting pictures of the setup on my website soon, will post a message when this is done.

Well, as they say, you can't always get what you want. A horizontal loop may not be what you put up for the time being. I use an inverted vee .... end fed, not a dipole. I have a self supporting pipe mast (45') in the front yard with a 2 el 20M beam on it. I wanted some kind of antenna I could use on all the other bands from 80M-10M as well.

What I ended up with was an inverted Vee end fed from the ground. I have 25' from the base of the mast to the front. I put #12 copper wire from the ground to the top of the mast, approximately 50'. I then have approximately 90' from the top to the garage at the rear of the lot, (a total of about 140'). At the front of the lot where the wire comes to the ground I have a sturdy 6"x6" post 3' above ground. The end of the wire comes to an insulator at the post. Mounted on the post I have a bird feeder, and under it a 1' square box in which I mount a SGC auto tuner. Beside the post I have copper ground rod with 8 buried radials converging on it. I feed the auto tuner with RG-8 coax which is also buried in the lawn as well.

It works beautifully! I have done side by side checks with the 20M beam .... and I can usually hear and work just about everything with the long wire. In the crunch of course the beam works the weak dx a lot better. The point is that if I didn't have the beam it wouldn't cramp my operating at all. The auto tuner is wonderful, and having it located out of the operating location directly under the long wire really improves the quietness of the antenna. I find this antenna is also with no doubt the best SW reception antenna as well.

You might want to experiment with just one pole first..... Another suggestion ..... one I have on my mind for the future is a delta loop ..... also with one pole. Good luck.

'

PS .... my second post! I forgot to address your question about putting the poles up. The one self supporting steel mast I have at the front of the house is about 45' high constructed of steel pipe about 6 or 8 in in dia. at the base .... like those steel flag poles. However mine is a tilt over with the hinge about 18 ft up. I just undo the bolt at the base, attach my simple rope block and tackle and lower the top right down into my drive way. The base of the fixed portion has 3/4' steel plate with 4 bolt holes. I dug a hole and carefully arranged 4 bolts in a kind of frame in the ground before filling it with concrete. The next step was to lift the whole thing and set the base and the 4 holes down over the 4 bolts! The black smith who welded the thing for me assured me he would be able to do the job. I was a bit skeptical at first when he came with a normal sized tractor with a front-end loader.

What he did was to fasten on to the mast at the balance point ..... like the "scales of justice". Then he lifted it up and with a couple of ropes a friend of mine and I rotated it when he lifted it up. It was literally vertical hanging with a cable from the bucket of the loader. A jiggle here and a jiggle there and it fell right on to the bolts I had cemented into the concrete!

I did this twice. I loved the tower so much that when I moved to another location ..... about 15 blocks away ..... I took the tower with me. I reversed the process and my black smith friend hauled it ..... a full 45' in one piece lashed to side of his truck! We chose to do this about 2am to avoid traffic. It looked like Sir Lancelot coming down the street hi hi. I put it up again in front of this house in the same way.

Now if you're going to put a pole into the ground the only thing you need is to be sure of is that the bucket can lift the pole .... eg weight wise. Dropping it into the hole won't be rocket science .... just have ropes tied near the top so you can secure it in a vertical position while you back fill and tamp it all down.

551. Wire for antenna ?

Yahoo group: SkyWires
Date: 2004-06-04 18:00:19 UTC
From: Michael
Topic: 551 Message: 551

I am moving to a new location and have the chance to buy new wire for the sky loop. At this time I am not sure of the "land size" available yet.

Still looking at rental properties in the Salem oregon area! (Hint, Hint . . . If anyone is from that area)

I have been using Green 14 AWG "Thhn" Stranded Wire, with good success, and it blends in very well with the trees.

I have been toying with the idea of zip cord or 450 ohm open ladder line and making a two turn loop.

I have also been thinking of using 450 ohm open ladder line as the wire.

I work mostly 80 ☐ 40 Meters with a little 160 tossed in.
So, I am looking at something that would be around 400-500 foot loop.

Anyone have personal experiences or any ideas they were thinking of trying? This would be a good chance for me to "Play" HI HI

Robert,

Very nice implementation of Cecil's notuner tuner.
Nice simple, easy to understand text, drawings
and photo... On your website

<http://iua2.net/notuner.html> you say,

"I have admired for years the fine example
provided by Cecil, W5DXP and his
'No-Tuner, All-HF-Band, Horizontal, Center-Fed Antenna'."

Yep, I've been _thinking_ about throwing up a big loop
for some time with a notuner tuner,
but non-ham concerns have taken
my time and energy for the last few years.
Now those seem to be passing and those
two small trees in the front yard are getting bigger
and closer to getting a big stealth loop attached
- finally. :)

Congrats to someone who actually did it!

One very minor quibble with a sentence on your page:
"...One characteristic of _balanced_ line
is that as its length changes, the impedance characteristics
at a given frequency also change..."

That is also true of _unbalanced_ transmission lines.
The input impedance seen at the transceiver end
varies as the line length to the antenna changes.
_If_ one could ignore losses, the input SWR
would stay the same, but with coax losses
would/do make the SWR and impedance look "better" :)
as the line is made longer/lossier.
A "notuner tuner" _could_ be built for coax,
but doing it with low loss balanced line
seems like a much better idea most of the time.
Has anybody done an unbalanced version?

Reg Edwards, G4GFQ,
has a nice set of small antenna
and transmission line freeware programs at

http://www.btinternet.com/~g4fgq.regp/

that are fun to play with and very educational
in how antennas in general terms
as one varies length, wire gauge, height,
transmission line type and length...
He has small (<0.1 wavelength) loop models,
but not big loops - yet.
I find myself using DIPOLE3 often.
Real life antennas in real life environments
are a bit more complex, but one can get
a feel for what happens with the models
faster than building all the variations,
but that could be fun :).

Cheers, 73,

Ron McConnell

556. Source for more 450 ohm ladderline?

Yahoo group: SkyWires
Date: 2004-06-07 13:20:58 UTC
From: nc9k
Topic: 556 Message: 556

Hello all,

My stock of commercial 450 ohm ladderline I bought in 1990 at LAMARSFEST is down to 15 feet. I now live in the middle of nowhere on 40 acres and want to order more commercial (not TV) ladderline online so I can connect to the 1080 foot loop I am putting up for 160 through 40M (I am keeping my 40M loop up for 20 through 10M - it really gets out!). If you know of good sources to order new commercial ladderline from please advise by posting on this Skywires site - others need to know as well.

Thanks,

Leland NC9K

Having trouble understanding this question - do you want commercial 450 ohm ladder line (not homemade)? There are many vendors for this.

<>
http://coaxman.com/webstore/Ladder_Line.html
http://www.wb0w.com/wb0winc/Cable.htm
http://www.radiobooks.com/products/ll4510.htm
http://www.universal-radio.com/catalog/cable/3028.html
http://www.davisrf.com/ham1/ladder.htm
many others....

Not sure what "not TV" means, unless you are saying you do not want 300 ohm TV twinlead.

567. Glad to hear of 1080 ft. loop success

Yahoo group: SkyWires
Date: 2004-06-10 15:01:38 UTC
From: nc9k
Topic: 567 Message: 567

Hello Keith,

I'm glad you got your 1080 ft. loop up. I've been gathering materials for mine. I've got the footprint measured out with tall trees as corner supports.

I've been using my 40M loop for 160 through 10M with my homemade coupler but, as to be expected with sub-harmonic operation of the loop, bandwidth is narrow and feed impedance is extremely high on 160 and 80M. A 1080 ft. loop will give me a much lower feed impedance, a lower angle of radiation and broader bandwidth on 160 and 80M.

I've been using a SB-220 for 80 through 10M when bands are weak. I've got a second SB-220 on the way that I will be setting up for 160M.

I have been involved with a daily upper Wisconsin, Minnesota and Michigan net on 3947KC at 4PM central daily. My 40M loop matches and/or out performs the other stations for reception and transmission on the 3847 net. You are welcome to join in. I'd like to hear your 1080 ft loop there! There is also an upper midwestern net on 3948KC 9:30AM central. I've just been listening to it so far.

Hopefully I'll be running full power into a 1080 ft loop on 160 and 80M this summer.

Hello Kenny,

I've had a skywire of sorts up for 2 1/2 years now. I've given your question some thought myself as I've considered what I might do to improve my installation. I'm not in a great rush (obviously) because it does work, and it works very well actually as a NVIS antenna. When I'm active on HF the two nets I most frequently am active with are state nets (MO), so it serves me well as a regional antenna, which is sometimes a challenge due to the hilly terrain of the Ozarks.

I currently have what I call a _slooper_ ...3-sided, supported at trees, heights roughly 50 (east), 40 (north), and 15 feet (west & the feed point), fed right out the window with ladder line. It also has about 15 foot of vertical radiation because of two reasons: (1) I split the window line several feet after it exits the window with the ends anchored to wooden blocks in the earth (preexisting treated 4x4's I found pounded into the earth nearly at grade level, 4 foot separation) and rising to the "antenna;" and (2) I wasn't overly concerned about the window treatment: I have a towel wrapped in plastic and this is sandwiched between the closed window, along with the 450-Ohm ladder line. Not the best condition for maintaining proper current balance! (I suspect the line becomes unbalanced at this point and begins radiating RF. This was my first HF antenna by the way.)

For field day last year a friend and I deployed a full sized 80-meter loop at roughly 30 feet. We are going to deploy the same antenna this year, but at 40 foot height. It works very well, so I've thought about what I might do to offer a similar home solution.

I am considering this solution:

Push-up poles on the order of 60 to 75 feet in height may be purchased (with pipe to extend your height, you have the ability to enter the cross-over point between NVIS and DX heights (1/4 wavelength)). It should be pretty simple to set these safely, guy as needed, and install each with a simple rope + eye hook at the top of the mast. (Some will argue for pulleys. If you go that route I'd recommend well made ones, perhaps marine

grade (ACE Hardware is said to carry good ones too). An eye hook is a lot more affordable and I don't think it'll destroy the rope leading through it. I plan to use _Silky_ wire (insulated # 26 copper clad stranded steel: cablexperts.com (best) or davisrf.com (2nd best)), 1000-feet<1 lb. (Has supported nearly an inch of ice buildup over a 400-foot run: good stuff!) Check your power handling capacity if you run an amplifier.)

Seems very easy to adjust height for regional work, or raise it for DX work. Easy to maintain as needed. Can be dropped with just step ladders (with due care for the fingers, etc.) This is my favorite idea. I'd like to hear what others offer.

Four towers is of course another solution. Big expense, a lot of labor. Not my preferred solution.

Trees are another obvious choice. If you have them in your yard of suitable height and climbability (mine are pretty easy to climb). It can be challenging working the antenna line over-and-around various branches. If you go this route give another yell here. I'm sure I'm not the only one that has come up with a tip or two along those lines.

Tuners are another question, off topic, but you may consider a balanced-z.

Take a look at your lobes too, to be certain you like the multiple lobes on the higher frequencies.

That is my 2-cents, good luck, good question!

Kenny,
My 40m loop is up 18 feet... it's the only configuration that my yard (and my spouse ;-) will support. I have "masts" (actually springy 3/4" square pine sticks) on my house and on a shed at the corner of my yard, one corner attaches to a maple tree, the fourth corner is thrown over the top of a pine tree and is counterweighted.

The wire "floats" in the insulators, and the tension is maintained by the counterweight at one corner - which is a 5 pound iron weight pulling down through a pulley. I drive mine with 300-ohm twin lead - and it gets out on 160 through 10 with my modest Kenwood AT-200 tuner. The longest contact on the fundamental 40m band has been near 1000 miles - that's where it's truly a NVIS source. On the higher bands it's gotten me everywhere I could hear - Europe, Africa, Argentina, Pacific islands. Also: NVIS is not too shabby - it enables you to make short-haul contacts in a wider range of propagation conditions.

73 and good luck!

Hi Jim,
At one time I also had a low loop and improved it's ability significantly by putting a second loop directly under the first one but buried in the ground by about 2 inches. My feed was between the two loops. For further info research Direct Discontinuity Ring Radiator or DDDR loops as the method of feed is quite different. I have had 80 meter loops as low as 6 ft which would knock my hat off when I walked under it. Because one method of feed has a grounded loop the noise level goes AWAY down. In fact you will think that your antenna is disconnected till you tune a signal. These low loops can be really big boomers.

584. Trees, a sappy Question

Yahoo group: SkyWires
Date: 2004-06-25 22:56:24 UTC
From: David Shrum
Topic: 584 Message: 584

My question is about trees, how do they affect the way the loop matches (SWR wise) at the radio?

Here is what I did during last winter; since it was cold my son and I put up the 530-ish feet of wire, now I know if we would have taken the time to support the wire away from the tree; that would be a lot better. But since it was cold and we were walking in knee deep snow, we used the outside of the trunk of the tree as our corner and used limbs as supports to hold the rest of the wire up. The wire was purchased in a 500 foot spool, #12 romax and we had to solder it together, we did make sure we had a good connection.

The main reason I am asking this question is the best SWR I can get is about a 3 to 1 match (without the tuner). Where I wanted to use it, 160 and 80, I can't even get my SWR meter to go to the set line, I have to use my tuner to 'tweak' the setting, then adjust it with the tuner to protect the radio; 40, 20 17, 15, 12, and 10 meter bands I can check the SWR then use the tuner to 'adjust' the SWR into a useable area for the radio.

Interesting concept! I am not sure how it would go in my yard, as it would involve chiseling up part of a patio.

Maybe if I present the choice: wrecked patio? twin towers?? she'll choose the towers ;-)

73 - and thanks for being a great group!

Hi Kenny,
Why not try a DDDR loop (Direct disconuity ring radiator).
I think for 40 M it is only 9 ft in diameter and about 6 ft high.
On 80 M it is maybe 15 ft in dia and 15 ft high Research it and if
you cant find anything get back to me and I'll give dimensions as I
have them on file.

589. 530 foot loop up!

Yahoo group: SkyWires
Date: 2004-07-01 05:18:42 UTC
From: nc9k
Topic: 589 Message: 589

Well, I got the 530 foot loop (160M) up yesterday at 35 foot height. It is oval shaped with 6 supports. It is constructed with 12ga. stranded plastic covered housewire and fed with 450 ohm ladderline at the south end of the oval. It tunes nicely with my homemade link coupler 160 through 10M. Corner supports are double 3 foot UV-resistant bungie cords with 60 inch long 1/4 nylon safety ropes alongside the bungies in case they break. I am using plastic electric fence corner insulators as the interface between the bungie cords and the antenna wire, with a single turn of 14ga copper wire trapping the antenna wire in the corner insulator slot. The entire antenna free-floats in the support system.

I ran 80M air tests yesterday afternoon. I linked up with K9RON on 3900 khz. He is located 45 miles northeast of me near Bergland MI. I ran the power going into my coupler down to 2.5 watts. He copied me at S9.

I ran additional tests with KC9DVO on the same freq. He is located 90 miles from me in Rhinelander WI. I had to turn the power up to 5 watts to get an S9 level there. I then kicked the SB-220 into the 530 foot loop and literally "jumped out of their speakers".

I compared receive signal strength levels on 20M between my existing 135 ft. loop (40M) and the new 530 foot loop. Both tuned flat. As expected, the 40M loop gave receive signal strength levels about 2 S units higher on my radio.

I ran the 530 foot loop on the 3973 khz breakfast club at 4am this morning. I easily copied mobile stations in Pennsylvania and Iowa that the other stations could not copy, including the net control station 1 hour away from me.

I think loops perform best when used on their second through forth harmonics. Hence I am keeping both loops up and applying them accordingly.

591. Loop questions

Yahoo group: SkyWires
Date: 2004-07-01 15:42:18 UTC
From: nc9k
Topic: 591 Message: 591

Hello Jim,

After carefully reviewing the numerous links and computer files on analysis of loops posted on Skywires it became apparent that horizontal loops re-develop high-angle radiation lobes if applied above their forth harmonic. They also have high-angle radiation on their fundamental freq.

I've been comparing receive signal strength on 20M by comparing the 2 loops (both tuning through my link coupler at almost identical settings) monitoring the Maritime Mobile Net on 14.300 as well as using both loops in the 14.340 net I check into Mon-Fri 8:30am CST. The 135 ft. loop consistently gives 2 S units higher receive signal on both my Atlas 350XL as well as my Icom 706MKIIG on all 20M signals. Both antennas are at the same height without any metal or other items to cause significant pattern disruption. These numbers are in agreement with the predicted angles of radiation for both loops.

The static chokes are a good idea. I've been pressing old SB-220 30K 5W power supply bleeder resistors into servive as loop static discharge resistors. I also use 3/16 inch sparkgaps (made from #12 solid copper wire) on my antenna selection knife switch on each leg of each 450 ohm ladderline. The resistors and spark gaps discharge through 3 feet of #4 solid copper wire into two 8ft. copper clad ground rods. I also intentionally use coated wire to help reduce precipitation static on the antenna wire itself.

Thanks for the questions.

Hello Erik,

The SWR on the 535 ft loop (using my homemade link coupler) is less than 1.4:1 across 160, 80, 40, 20 and 10M (except 160M, where it rises to about 1.9:1 below 1900 khz). I will be mapping the new antenna with my General Radio Impedance Bridge once I another free day in my work schedule. I will post the results here afterward. Thanks for asking.

Roger-
not aware of a NET, but it's a good thought. I can tell you about the tuner I use. It is an old Dentron unit, and will match about anything you throw at it, with or without 1.5KW! It is a model MT-2000a. I've owned others, too. The old Murch is a beauty, but the early ones won't cover 160M. The Heathkit SA-2060A is good, also. I use an external meter, so the lack of one doesn't bother me. If you buy one of the aforementioned (I am sure there are others!) you should have no need for another in the shack for the rest of your ham career. PS-- I bought my old Dentron (used) for the same price as a new MFJ-949E. My guess is the old Dentron will still be happily working when today's MFJ is filling a landfill somewhere. Don't get me wrong, I have an MFJ, too, but the loop can present some real extreme impedances, and a less expensive tuner may have problems with that. Just my experience, and always "your mileage may vary"! 73- Greg Schippers, KC8HXO

Hi Roger,
Haven't heard of any net or anything like that, but it
is an interesting thought.
I use an old Heathkit SA-2060A, 2kw tuner that I got
used from a swap net on 40 meters. It will tune
anything and handles my SB-220 without batting an eye.
Good luck finding one though!
Check out the "product reviews" at Eham.net....lots of
info about all kinds of tuners there.

Topic: 594 Message: 597

I have used/owned three different MFJ tuners successfully. Two models have a variable inductor and one a tapped inductor. They are OK. Not great, but OK. The quality of construction leaves something to be desired.

I would recommend getting the larger components (1.5kw vs. 300w), it is far easier to achieve a tune and potential arcing will be less of a concern. I also like roller inductors because they always enable me to find a very good match. But if the tuner is properly matched to your antenna (with regard to its tuning range) you should find the tapped coils work well enough.

You might also consider Ten-Tec's tuner. Or purchasing their air variable capacitor kit and 28 uH roller inductor and making your own (mine is laying in pieces awaiting me to set aside time to assemble it, so I can't push on that front too hard, hi-hi).

If memory serves, a pair of Ten-Tec's capacitor kits is $100 ($50 each) and the roller indictor is about $80 or $85. $200 is a fair bit of change, and you don't even have an enclosure or hardware yet, but it will be a solid transmatch once you finish it!

Hi Roger:

Since you are at the research stage vis-a-vis a tuner and you may be looking at a loop (balanced) type antenna (although you didn't specifically mention that) I would suggest looking into a tuner designed with a balanced feed objective. In early days balanced feed systems were predominant and transmitter/antenna matching systems were designed with this in mind.

Since the 60's the transmitter/antenna systems have been dominated by unbalanced feed systems using coax feed lines. It is possible to feed balanced antennae such as dipoles and loops directly with coax using various tricks. However, multi-band operation is difficult.

In more recent times there is renewed interest in feeding balanced antennae with balanced feedline and some of the old advantages are being realized. However, no balanced antenna tuners were still being made. The solution has been an add-on solution; without exception all the major manufacturers simply added a balun on the output side of the unbalanced tuner. This add-on solution does not always work very well since the balun by nature does not work well at high and complicated impedances ..... especially with high power.

At this time a couple of manufacturers are starting to produce antenna tuners designed primarily for balanced feed systems. Palstar makes a beautiful model made to handle high power..... and MFJ I believe has one as well. In both units they place the balun between the transmitter and the tuning unit instead of between the tuning unit and the antenna feedline.

In early days a common approach to designing a tuner was to use the link system rather than a balun ..... but as far as I know there is no commercial manufacturer (except for the QRP Z-match) using this approach. I use a link type balanced tuner designed and manufactured back in the 50's and early 60's that tunes all amateur bands with no switching! It is however limited to handling about 100 watts or so. It is called the KW E-ZEE match and uses the same principles of design as the QRP

Z-match.

I expect to see more commercial development along these lines ..... good old ideas always have a way of re-emerging.

Hi Ron:

The approach to designing a balanced tuner using a balun between the transmitter and a kind of double L tuned circuit is not the easiest way. You might want to look at the venerable Z-match approach that uses a special kind of L circuit with an inductive link. The greatest advantage is that it avoids the complications of a variable inductor (roller type or switched). If you look on the internet for "KW E-ZEE match" you will find plenty of details; this approach uses 2 inductors and links and tunes all bands with no switching. A single coil version is demonstrated at the following site:

http://www4.tpgi.com.au/users/ldbutler/SingleCoilZMatch.htm

Thanks for the info.

How do you keep the #18 from getting jammed between the side of the pulley roller and the pulley frame?

Do you use a special type of pulley?

Best wishes,

Mike- just another Idea.... I also use a rubber bungee, but I use a nylon wire-tie through the end of the bungee where the S-hook would be. (remove the s-hook). I have had great success with this set up. Sure, after a few years the ny-tie will give in and break, but by then the rope is about shot, too. PS- I use mason line for rope. I am sure it's not the best, but it works for me. Best to you--

I am using small enough pullies that it hasnt been a problem.
I put up the pulleys to experiment with "rotating" my loop by
sliding the feedpoint to different positions. I didnt see any
useful difference in directionality by moving the feedpoint. Ill
try it again later with some good reference antennas and see how
that works again before I give up on that idea.

You really dont need the pulleys at all. I used plastic insulators
that you get in the SWL antenna kits from radioshack for a long time
before I switched to the pulleys.

The bungees are a good idea though.

Hi Loop fans around the world,

I have 2 questions:

1. Has anyone out there ever tried to build a multiband loop antenna that the 746 Pro, 756 Pro
or Pro2 could tune with *only* the built in antenna tuner?

2. Has anyone ever used a 3:1, yes 3:1, balun from http://www.antennasmore.com/baluns.htm, made specifically for matching coax to single turn loops?

I have seen many multiband loop antennas that use external antenna tuners, but I have never seen one
that uses just the internal antenna tuner of the 746/756 Pro or Pro2. I am interested in 100 watt
peak power only.

Thanks in advance.

Hi Tom,

I have 2 answers:

#1
I am using a 75 meter Full Wave Delta Loop.
It will tune from 6 - 75 meters using only the built in antenna tuner in my Yaesu FT-920.
I am using 54' of 75 ohm RG 11 coax from the loop to a PL 258 connector , Then I finish the run to the shack using 50 ohm coax, I chose LMR 400.
I use a 1/4 wave inverted L antenna for 160 meters.

#2
This is the first time I have ever seen any reference to a 3:1 balun.

NOTE: With (Matching) Transformers “Baluns” it is the "Ratio" of the Squares
of the Number of Turns that 'defines' the "Ratio" of the Matching Transformer.

Here are some straight math common examples:

* One to One "1:1" = (1X1) : (1X1) = 1 Turn to 1 Turn

* Four to One "4:1" = (2X2) : (1X1) = 2 Turns to 1 Turn

* Nine to One "9:1" = (3X3) : (1X1) = 3 Turns to 1 Turn

* Sixteen to One "16:1" = (4X4) : (1X1) = 4 Turns to 1 Turn

* Twenty-Five to One "25:1" = (5X5) : (1X1) = 5 Turns to 1 Turn

* Thirty-Six "36:1" = (6X6) : (1X1) = 6 Turns to 1 Turn

So a 3:1 balun would have a Turns Ratio of 1.7320508 Turns to 1 Turn - Very Interesting!

Ace - WH2T

Tom,
I have been using my 280 foot loop for over a year
with the internal tuner of my 746 Pro. I have used two
different 4:1 current baluns and both worked very well
(note: I am also able to use the loop/internal tuner
on 6 meters, but only at about 50 watts).
The tuner works just fine on 80-10 meters for full 100
watt output and 1:1 swr.
My first balun was a W2AU cheapie and it worked fine,
but I also like to be able to run a linear so I picked
up a High power balun from DX Engineers and it works
great with just the internal tuner and with the high
power amp/tuner.
My feed is simple: 67 feet of 450 ohm balanced line
(quarter wave of the antenna resonant freq.) to the
balun and then 50 feet of RG8 to the rig.
It's awesome to be able to change frequency and bands
and not worry about the antenna/tuning!

I'll try something similar. I'm running out of space for a single turn loop so I may have to try
2 turns of 140 foot square loop. Any Idea how that would effect the L=1005/MHz formula?

Thanks Rick

I have been using a 160 meter loop skywire with 530 feet of wire and 200 feet of 450 ohm ladder line connected to a Air-Dux #2B009 BALUN setup for 4:1. From there 6 feet of RG-8X connects to the ANT-1 connector on the rear of my PRO II and allows 1 to 1 SWR match on all HF bands and the low end of 6 meters. When I use my Heathkit SB-1000 and Heathkit SA-2060A tuner I use the Internal 4:1 BALUN and 2 feet of 450 ohm ladder line from the window feed through to the tuner rear connector. No problems encountered with 1K power levels on 160 to 10 meters.

Nice arrangement, Scott. I have never bought ladder line,
but I'm about to take a trip to HRO(Ham Radio Outlet). It's
about time I learned what low loss is all about.

Thanks.

Hello Tom,

When I was still doing military design work at Northrop I developed a 2.25:1 ratio twisted-wire line balun by combining a 9:1 (3 to 1 turns ratio) with a 4:1 (2 to 1 turns ratio) on the same core for a 30 Mhz to 500 Mhz broadband power amplifier design of mine.

625. Skywires and trees

Yahoo group: SkyWires
Date: 2004-07-24 12:46:28 UTC
From: lochnessguide
Topic: 625 Message: 625

Hi all, fine group.

My question is about how the skywire antenna reacts (or not) with trees.

There has been a lot of valuable information posted here about insulators, bungee cords, pulleys, ropes etc. but what if it is not possible to use such attachments? I appreciate that if you have a regular lot and four towers this is probably fairly easy and the best way to go, but what if you are experimenting with various lengths in woodland?

For example I have an area of birch woodland in my garden backing onto more woodland. The rear woodland, off my lot, is crofting land and no-one minds a wire in the trees (or at least I can get away with that) but not attachments complete with insulators. But since I plan to use conduit wire which has plastic insulation, are the insulators and attachments really necessary? Has anyone tried just putting the wire over the trees, creating the best loop you can with a given length and attaching it only at the feedpoint? That is, just passing the wire through forked branches in a rough circle as high as possible round and back to the feedpoint which can be attached to a tree near to the shack.

Do any of you do this and what are the results?

My trees are birch trees that are around 40 feet or so but wave about a bit near the tops so I was planning to just pass the wire around and back to the feedpoint where I could use some elastic rope or bungee cord to keep some tension. I could do this, but being up a ladder for long may be risky at my age :) and firing arrows/slings usually is not very successful as it just lodges on other trees - the woodland is fairly thick.

Does the antenna react with the trees even using insulated wire? Has anyone any ideas or experience on this?

Keep up the excellent work.

Ray

I have a 160 meter loop with 530 feet of insulated
wire and there are points along the wire run where the
wire runs through trees and is in contact with the
limbs and foliage. I have found that as long as the
wire is insulated this has no effect on performance.
Also at a few points where it was required to pull the
wire out from under limbs in order to get the wire
above them I used a long rope across the wire with no
insulator and left them in place with no effect even
when wet. I have a roll of wire 1590 feet long I have
ready to put up for a 3 X 160 loop, which will be put
up as you describe in your project. I had planed on
putting it up last fall after the leaves had fallen
but I had medical problems that canceled the project
and I am still recovering from the required surgery.
Hopefully I will be able to do it late this fall or
early winter.

Hi Ray,
over the years I've used insulated wire thrown over
branches for antennas many times. It's better than
nothing and it does work but remember that a live tree
is a waterpump pumping water from the ground to the
leaves. It tends to be lossy. Also if you run much
power into a high impedance antenna the voltage on the
wire can burn thru the insulation effectivly shorting
it to ground.
Higher freqs are more effected by this than low ones.
If you don't use a lot of power and use the lower
bands it should work fine. The main problem I had was
the wind bending the trees, tearing my wire. You might
try a large rubber band where the wire connect to the
tree to allow movement without letting the wire sag.
I hope this helps.
73 Brian ka2cxg.
ps I've seen soom people here sign with "72" what does
that mean?

628. Re: [SkyWires] Skywires and trees

Yahoo group: SkyWires
Date: 2004-07-24 16:26:05 UTC
From: Erik Weaver, n0ew
Topic: 625 Message: 628

My main concern would be the health of the trees. A wire around a tree with tension on it will cut into the bark and this will harm the tree. I would anticipate there is some absorption of the RF signal, but at HF I don't know if that would be a measurable amount or not.

So far as I know one is better off placing a screw into the tree. Anything encircling the tree will either cut into, or impede future growth of the limb/trunk.

A local arborist (SP? - tree specialist) should be able to provide you detailed information about anchoring to a tree properly.

630. Again, feeding the loop directly by coax

Yahoo group: SkyWires
Date: 2004-07-24 20:26:31 UTC
From: spninesoy
Topic: 630 Message: 630

Hi

I would like to exchange experience about feeding the loop directly with the coax, and using a balun or an ATU at the other end.
Did somebody try this also for harmonic bands?

Currently I'm using a 40m loop fed with 75ohm coax and next by 50om coax, and I get the SWR less than 2:1 at 7 and 14MHz. On 21MHz I have to put (with a switch) a coil in series at the point where the two coax join. So there is no need to use an ATU. This design is very succesful.

I hope to get the same result with the new 80m loop, which I intend to set up. The feeding point will be very close to my shack (loft) so there would be not enough distance to use 1/4WL 75ohm coax transformer, since for 80m it should be 20m (65ft)long. I can arrange maximum 7-8m (25ft). Anyway that design wouldn't probably work properly on all bands.

I plan to feed the loop with 50ohm coax and use a 1:4 or 1:6 balun at the end, which would theoreticaly match the high impedence of the loop (at the higher harmonics) to the standard 50ohm. (Except if there is too much reactance...?)

I definitely won't use the ladder line. I had bad experience with in the past, due to the lack of the appropriate inductively-coupled balanced tuner.

Did anybody tried the coax feed for multiband use? What are SWRs on the harmonic bands? Or should I use 75ohm coax instead of 50ohm and an ATU at the end?

Thanks for help and sharing your experience.

631. Balun placement

Yahoo group: SkyWires
Date: 2004-07-24 23:56:30 UTC
From: Jeff - N3YEA
Topic: 631 Message: 631

Greetings All,
I'd like to pose a question.. where would the best place to locate the balun be ? close to the antenna or close to the rig ?
I have an 80 meter loop up at about 30 feet. Fed with 100 ft. of 450 Ohm ladderline. I get no rf in the shack except on 40 meters.
On 40 meters I swamp everything in the vicinity, 2 meter rigs, power supplies, tnc's etc..etc.. So - I am planning on putting a 4:1
balun in line. Should I get a balun and place it outside below the loop and run coax into the shack ? or would it be better to by a
tuner with a built in 4:1 balun in it ?

Thanks es 73,
Jeff - N3YEA

632. Re: [SkyWires] Again, feeding the loop directly by coax

Yahoo group: SkyWires
Date: 2004-07-25 00:05:14 UTC
From: Dr.Ace Ratliff
Topic: 630 Message: 632

Hi Alex,
I am using a 75 meter Full Wave Horizontal Delta Loop.
I was in a hurry when I put it up and I accidentaly used the velocity factor of the 50 ohm coax instead of the 75 ohm coax to figure the length of the quarter wave matching "Q" section. Since it was ready to go when I discovered my mistake , I thought I might as well try it instead of cutting the length of 75 ohm coax down to the 42 feet as given by the correct formula.

I have 54 feet of RG-11, 75 ohm coax that runs from the loop to a PL258 connector then I am using 50 ohm coax into the shack.
My Loop antenna is flat 1:1 VSWR around 3.875 Mhz and rises to about 2:1 SWR at 3.75 and 4 Mhz . So I cover the entire 75 meter phone band without using a tuner.

I can tune 6 thru 75 meters using a manual or built in automatic antenna tuner.

The following Info is taken from
http://www.bloomington.in.us/~wh2t/loop.html

The length of the 75 ohm coax is most important. It will be used as a Q section.
To determine the length to use, Use this formula "Length in feet = 246 x VF / Freq in Mhz"
VF = the Velocity Factor of the coax. So multiply 246 by the Velocity Factor of the coax , Then divide by the frequency .

If you use RG59 or RG11 with a Velocity Factor of 0.66 , For the 75 meter band the Piece of 75 ohm coax should be about 42 feet long , It doesn't need to be exact . RG59 and RG11 coax usually have a Velocity Factor of 0.66 , Foam dielectric coax such as RG6 might have a Velocity Factor of 0.81 or more.

Put a PL259 coax connector on the unused end of the 75 ohm coax, Screw a PL258 double female coax connector onto this PL259 coax connector. Then connect 50 ohm coax to the other side of the PL258 double female coax connector, Use any length 50 ohm coax needed to reach your Transceiver.

Hi Jeff,
I think the best solution to the RF in the shack is to place the balun outside at the bottom end of the 450 ohm line then run a piece of coax from the balun into the shack.
I have tried it with a 75 meter double extended Zepp antenna and it worked well.

From: Dave
Topic: 630 Message: 634

I wish I could be that lucky on SWR, on 160 and 75/80 with my tuner I can get a match that won't fry my radio but if I dial about 30 ish kc either way, I HAVE to retune, it does get better the higher the frequency gets; my loop [about 530 feet] is using the tree trunks and limbs to keep it up, and I do believe that is why I am having a problem with SWR. It does work, but I have to believe if/when I move it so I have some of the wire away from trees, I expect to see improvement, but for now that is just speculation.

Hi Jeff. Your question/statement begs the question, what are you using now to couple the 450 ohm ladder line to your transceiver? It doesn't sound like you are presently using a tuner or a balun!

If the intention is to operate a balanced antenna such as a loop or dipole on more than one band the general practice is as follows:

- use low loss balanced feed line to minimize power loss and feed line radiation.
- bring the balanced line as close to the operating position as possible.
- couple the balanced feed line with an antenna tuner to the 50 ohm unbalanced output of your transceiver.
- if you're going to use a balun between the balanced line and the tuner keep it as close to the tuner as possible.

The majority of present day antenna tuners are unbalanced circuits designed to match an unbalanced load to the transceiver. They use a balun on the output side to accommodate balanced feed (an after thought). There are now a few tuners on the market designed primarily to couple balanced feed lines (rather expensive). These tuners use balanced tuning circuits followed by a balun on the low impedance side (where it works best) to feed the transceiver.

Although the preceding is the general practice it is not the ultimate. The ultimate system would be to locate the balanced tuner as close to the antenna as possible. The tuner would then be connected by good quality coax back to the operating position (ideally bury the coax). Of course, the tuner would have to be one of the modern automatic antenna tuners. This system would provide minimum loss, minimum antenna/feed line interaction, minimum RF in the shack, Minimum noise pick-up, and minimum fuss in operation. I use such a system with a 40M delta loop (vertical)

which loads all bands, 10-80M, using an SGC automatic antenna tuner. No fuss, no muss; it is as simple as operating into a dummy load and it works great.

Subject: Re: [SkyWires] Again, feeding the loop directly by coax

I wish I could be that lucky on SWR, on 160 and 75/80 with my tuner I
can get a match that won't fry my radio but if I dial about 30 ish kc
either way, I HAVE to retune, it does get better the higher the
frequency gets; my loop [about 530 feet] is using the tree trunks and
limbs to keep it up, and I do believe that is why I am having a problem
with SWR. It does work, but I have to believe if/when I move it so I
have some of the wire away from trees, I expect to see improvement, but
for now that is just speculation.

Try adding a few more feet of feed line. It sounds
like you have a feed line length where the high
current is right at the end of the length you have
now. With an antenna that that has a feed point not
matched to the feed line there will be high and low
SWR points along the line depending on the frequency.
adding and removing a few feet of the feed line will
move the high SWR point away from the feed point of
the antenna (or feed line) tuner.

Dr.Ace and Scott Erwin,
Dr.Ace I guess I miss lead you by not saying that I am using 50 ohm, RG8 coax and not 75 ohm like the post I was replying to.

Scott I am using about 49 feet, it was a length that I had laying around, I didn't measure it just used it, and most of it was wadded up on the floor, I'm guessing about 30 ish feet, it was not coiled up in a loop, I learned better from my CB days, trying not to make a choke out of the coax.

Looks like I am answering myself, but I'm not, just additional info; I cut off about 3 feet, about all that did was to change the setting on my tuner, about the only band I couldn't 'tune' a 1:1 match now is 17.

Hi Roger
I am using a 989c MFJ with my 1080' loop and it works fine but a lot of folks say there atr not that good, and Iam sure there are better ones out there.
I some times use a home made balun and some times the one in the tuner, they both work from 10 to 160 m and I only have a 100w out so no problim there. Hope this helps.

I've used a SGC-237 but with only limited success. It did not tune my loop. I've not tried it on much else since then.

I have used MFJ manual tuners with great success. I find I prefer the ones with roller inductors as opposed to the ones with a tapped coil, because the roller inductor is fully variable.

I have only used "T" configurations, in the C-L-C pattern (Capacitor-Inductor-Capacitor). These have the inductor (coil) going to ground and attached between the two capacitors. One of the capacitors is connected to the antenna and the other to the transceiver. You can think of this as a more or less straight line connection between the transceiver and the antenna with the inductor going to ground between the two capacitors.

Works great. Some like the L-C-L design better (Inductor-Capacitor-Inductor) because it has better harmonic supression. I feel that since the newer rigs have such great harmonic supression in their base design I'd rather have the somewhat greater tuning range of the C-L-C vs. the L-C-L design.

Get the largest value capacitors you can and an inductor on the order or 28uH or so. Capacitors on the order of 400 to 500 pF should work very well.

Of the MFJ tuners (more properly called a 'transmatch' because it transforms the impedance of the antenna to match the transceiver) I have used I so far prefer the 962-D. However, that is the largest component tuner I have used. That may be why I have liked it best.

I have bought all mine used and the turn counters for the roller inductors ahve all been broken. They are still quite easy to use even without the turns counter.

Hopes that helps a little.

Hi Roger,
I use a MFJ-989C the main reason I chose it over most of the other brands is it uses 6KV variable capacitors, many other brands use 4.5KV variable capacitors. I would still like to have a heavier duty antenna tuner.
Also MFJ calls the 989C a 3 Kilo Watt Antenna Tuner, thats a joke. It will only handle about 900 watts on the 160 meter band before it arcs the variable capacitors.
F.Y.I. I bought this unit brand new, not used.

Hi Roger:

I use an old tuner which is no longer made, the KW-EEZE Match. You will find descriptions of it if you search it on the internet. It uses a design called Z-Match which was more common back in the 50's and 60's. Unlike most present day tuners it is inductively coupled which makes it ideal for feeding balanced antennas such as loops and dipoles fed by lines like 450 ohm ladder line. It does away with the need for a balun .... which by the way does not work at its best at impedances above 100 ohms.

The only commercially made tuner using the Z-Match circuit is a QRP unit .... again if you search the internet I am sure you will see it. They are very easy to construct if one wishes to homebrew. The Z-Match circuit is simply an L network (a T network is basically 2 L networks). The network is simply a series variable capacitor and a fixed inductor connected between the transceiver output and ground. The antenna is connected to the L network by an inductive link coiled around the inductor. The ingenious method of varying the inductance (no mechanical switch or roller inductor!!) is to place a second capacitor in parallel with the inductor. The capacitive reactance cancels the inductive reactance thus varying the inductance of the fixed coil!! It works like a charm ..... 2 controls and it tunes all bands 80-10M with no switching or mechanical roller inductor!

If you want to use coax input you simply have to ground one end of the link. I have had this unit for at least 20 years and it still works like a charm and is totally reliable.

Hi,

A 3:1 balun would have a Turns Ratio of 1.7320508 Turns to 1 Turn

Three-to-One (3:1) Balun.
Primary (Antenna) Turns to Secondary (FeedLine) Turns.
12 Turns to 7 Turns

OR 17 Turns to 10 Turns
OR 24 Turns to 14 Turns

will give an impedance transformation ratio of about 3:1

If you are winding it on a Toroid core
First: Use large enough wire for the Primary (Antenna) Windings to
cover 85%-99% of the Toroid's Area. Or, "Space Evenly" the Primary
(Antenna) Windings 'far enough apart' to cover 85%-99% of the
Toroid's Area.

Second: Wind the Secondary (FeedLine) Windings over the Primary
(Antenna) Windings. Use the same size wire "Spaced Evenly" to wrap
the Secondary (FeedLine) Windings to cover 85%-99% of the Toroid's
Area.

647. RE: [SkyWires] Feeding the loop directly by coax- Addition

Yahoo group: SkyWires
Date: 2004-07-27 01:37:35 UTC
From: Scott Erwin
Topic: 630 Message: 647

You might want to build a simple device to install different lengths of feed line to be switched in and out according to band/frequency as required. You will need some switches and feed line cut to different lengths. The following link will give you the information on making one.
http://www.qsl.net/w5dxp/notuner.htm
Go down the page a little and find the "Ladder-Line Length Selector for our all-band dipole. It shows using ladder line but coax will work just the same. With coax you wont need the relays as you can have it in a box right at your desk. Just don't make the coax coils to small.

From: kl7r
Topic: 625 Message: 648

> ps I've seen soompeople here sign with "72" what does
> that mean?

Some folks who use QRP (low power) sign off with 72 instead
of 73. (Sort of a "Best Reguards fellow QRP enthusiast")

I have used wires through the trees.

It doesnt seem to have a noticiable effect on how the antenna
performs as long as you have insulated wire.

If you have un-insulated wire however and a tree branch
touches your antenna, it will seriously un-balance your
antenna and you will get "rf in the shack" which is a
bad thing if you are into psk or other sound card modes.

(RF in the shack is also a bad thing if you dont like having your
family yell at you about their electronics going blatzo or having
your lips get burned on the microphone when you transmit)

649. 2/3 sized loop calculations

Yahoo group: SkyWires
Date: 2004-08-02 19:56:47 UTC
From: bambazonke01
Topic: 649 Message: 649

Dirk,
Here is how I calculated the loop size for my small lot.
This loop is available commercially as a "Super Loop" from ? but I never buy when I can build an antenna.
The loop is a vertical triangle with the base along the top and the apex hanging down. It could be flat or even a horizontal square.
The feedpoint at the bottom has a 3:1 or 4:1 balun and is fed with 50 ohm coax.
The top center is broken with an insulator and has a 29 ft length of 450 ohm twinlead shorted at the bottom end connected across the insulator.
This antenna works as a loop on 80 M but works as 2 one wave lengths fed in phase on 40 M.
What are the dimensions?
1 wavelength at say 7.1 Mhz=984/7.1 =138.59 ft
If this length is doubled and used on 80 meters as a loop
Then Freq(for a loop) =1005/(2 x 138.59) =3.626mHz.
The 1/4 wave stub = 234/7.1 and multiply by .88 (vf of twin lead) =29 ft.
The perimeter of the 80 meter loop for 3.626mHz =277.18 - (2 x 29)[2 x 29 = the length of wire in the twinlead]
= 219.18. Say 219 ft.
If the top span is made 101 ft and the legs 59 ft
Then the balun wil hang 30.5 ft below the top center insulator.
The 29 ft shorted twin lead can have it's end tied to the top of the balun with a short length of string.
Any thing tuned for 80 will also work on 20 and 10 meters
On 40 meters the stub automatically acts as a switch and opens the connection across the insulator so the antenna works differently.
If it works on 40 it will work on 15 as well. A tuner will take care of 10 18 and 24Mhz.
I'll put one together in the next few weeks and try it out. I think this will also work as a 55 ft square on a horizontal plane. The 219 ft loop can be pulled into almost any shape but the bigger the enclosed area the better it will work.
I hope my calculations are correct.

From: radioham48082
Topic: 650 Message: 650

Just wanted to say how much I enjoy all of the posts. I threw up a piece of insulated 12 ga. wire about 300' long in kind of a delta configuration loop fed by an AH3 Icom coupler. Coupler is 6 feet off ground. Wire goes up about 40 feet, and over from tree to tree to form the delta and back down to the coupler. It works unbelievably fantastic on 160, 80 and 40. For DX, my ground mounted, well counterpoised Butternut vertical works better. Understandable! On 160-40, I consistently get 3 S-units (18 Db) over the vert. Fantastic! Someday I will get one up even squarer and higher. The Loop-Our best kept secret! Great group, keep up the good info exchange.

Hello All
I am new to the group and have just put up another loop. I have been experimenting with loops for a while and I am so pleased to find SO much information here. My old loop was 530 foot #14 wire Ran through the trees up about 45 feet feed with 450 ohm ladder line into a palstar 1500cv (new palstar at4k on order) New loop is 405 feet long #14 Grey (good color by the way almost invisible)..
The shorter loop is in the clear not touching any limbs. I am having trouble tuning it on 160.. 1500 watt tuner flashing at caps with 500 watts! Possible high impedance or what?? Now it should be 3/4 wave on 160 1 1/2 wave on 75 and 3 waves on 40. Some signals seem to be stronger on 75
but it is hard to tell due to solar storms etc last week or so.
has anyone tried a 3/4 wave loop and had the same problem??

Thanks for the input Keith
your 1080 foot loop sounds great.. My next project is to build one
that size. I have 2 oak trees on open space next to my house the
land is not used at all. If I run the loop up to the trees and back
I would gain an additional 65 feet in height also. However the loop
needs to have a low profile. The field is covered in dry grass..Does
anyone know if the loop breaks can my 600 watts start a fire????

Hi Mike:

Interesting that your wire antenna will build up all the static electricity! Well I think an easy way to deal with that would be to place a high value carbon resistor from each side of the 450 ohm line to a ground. The high value resistors .... say 100K or more ... should drain static build up without affecting the operation of the antenna/tuner/feedline. Some will advise a spark gap arrangement .... but it makes noise .... and requires a voltage build up sufficient to jump the gap. They are better arrangements for lightning protection. A good solid spark gap arrangement in parallel with high value resistors to bleed static should do the job.

656. Tuner Required ??

Yahoo group: SkyWires
Date: 2004-08-11 12:51:33 UTC
From: ve6drw
Topic: 656 Message: 656

I am new to loop antennas and have the space to install one. If I create a 530 ft loop (resonant on 160M), will I need a tuner to match the antenna on the other HF bands? I have space for a larger loop (upwards of 1000 ft). Is there any advantage to making a larger loop? If so, what length should I make it?

I assume most loops are fed with 450 ohm ladder line. Should I use a 4 to 1 or 9 to 1 balun to match my radio?

Any advice would be appreciated.

Thanks

Dave

You really do not have a problem as long as you're feeding your loop with a 4:1 Balun and you have a proper station ground. Using a Balun one or the other leads will be connected to ground providing a static drain for the antenna to the station ground. You can check this by hooking up a volt/ohm meter to a Balun and reading a direct DC short between all leads. This is not a RF short however. When you disconnect your antenna when not in use you should provide a large jumper wire between the antenna and the station ground so the static can drain off to prevent the static buildup. With my station setup I have two ceramic feed through insulators from the window for 450 ohm ladder line from the antenna to the back of my antenna tuner. I use the internal 4:1 Balun. I also have a ceramic feed through insulator for the ground connection to a 10 foot solid copper rod which is also connected to another ground rod below the power meter several feet away by bare solid 10 gage copper wire buried several inches below the soil. When I disconnect my antenna and unplug my equipment I also simply hook my shorting jumper between the ceramic feed through insulators for the antenna and the ceramic feed through insulator for the ground connection. There will only be a very short time that the loop will not be connected to ground as you disconnect the feed line and install the jumper.

From: Scott Erwin
Topic: 656 Message: 658

You will need an antenna tuner if you want full coverage of all HF amateur bands. If your transceiver has an internal antenna tuner you will need A Balun and as 4:1 Balun are easy to build or buy and come in most antenna tuners that should be your choice. Some internal antenna tuners will not be able to handle the mismatch (more than 3 to 1 SWR) on some frequencies. If you do not have an external antenna tuner now is the time to build or buy one! Also do not waste money on a flimsy 300-watt tuner. Sooner or later you will want an amplifier, which will require obtaining the larger tuner anyway. Something else about antenna tuners you should know. The cheap 300-watt or less tuners are not built very well and have loss through them. Large tuners must stand up to high power levels and so have silver plated inductors and proper sliding contacts on the capacitors. Even if you never plan on using high power the low loss through the large tuner makes it worthwhile to go ahead and get one, even if your only running QRP power!
If your going to the larger loop unless you can go with a full 3 times 160 loop at 1590 feet of wire your wasting your time and effort. The only reason to go larger than a full 160-meter loop is to improve operation on 80 meters. On a 160 meter loop the 80-meter band will be an even wavelength and so there will be losses on that band and places where tuning it will be difficult. You will not see any gain on 160 meters, as the antenna is simply to close to the ground, even if you could get it up to 200 feet.

Dave, I've been told theres no use for makeing the loop larger, so in my case I wont go to the extra work. You will need a tuner to tune and transmit on the other HF bands, but its worth it. I run my icom 718 and an mfj 962 d tuner which has an internal 4.1 balun, and use an ameritron al-811h 800 watt amp.So when getting a tuner, get one thats heavy enough for an amp if you decide you want more power some day, I wasted my money on a 300 watt tuner and it was good but I had to get a heavy one when I bought my amp. This is a learning experence for me every time I do something new, hope this helps, 73's Mike w7kol

Hi Dave
There is an advantage to a larger loop..When the loop is 2 times resonate frequency the Angle of radiation decreases. So in other words a 160 loop is a cloud burner. A loop 1060 feet on 160 should have a better radiation angle and be better for dx.

661. Re: [SkyWires] Tuner Required ??

Yahoo group: SkyWires
Date: 2004-08-11 21:47:16 UTC
From: Dr.Ace Ratliff
Topic: 656 Message: 661

Hi Dave,
I have used a 1 wavelength 160 meter loop, a 2 wavelength 160 meter loop, and a 3 wavelength 160 meter loop antennas. I never intend to again put up any loop antenna larger than 530 feet. I have experimented on other frequencies with up to a 10 wavelength loop antenna.

I know what the antenna modeling software predicts and I also know how the antennas behave in the real world. Also, If you are a big DXer, I believe there are better choices than a loop antenna for the 160 meter band.I am a rag chewer and the loop antenna serves my purpose ideally.

I know there are people in this group who might disagree with this next statement But, experience is a good teacher. A loop antenna should be an odd multiple of wavelengths i.e. 1 , 3 , 5 , etc...
An even number of wavelengths causes the loop to be a higher impedance and more difficult to match. I don't care what the antenna modeling software predicts, I have been there and done that, I speak from real experience.

P.S.
I have personally used a 160 meter band Horizontal Full Wave Loop antenna with very good success. I worked all 50 states and several countries with 100 Watts using the antenna on the 160 meter band. With a good antenna tuner the antenna will work 6 thru 160 meters.
I currently use a 75 Meter Full Wave Delta Loop on the 6 thru 75 Meter bands with a tuner, and I use a 1/4 wavelength inverted L antenna for 160 meters.
I hope this info is helpful.

From: Erik Weaver, n0ew
Topic: 662 Message: 663

Hello,

The answer depends upon where you wish to strengthen your RF signal. I'm assuming you are talking about a horizontal loop. The following will not apply if you are talking about a vertical loop...

Your double loop sounds to me like a NVIS design (Near Vertical Incidence Skywave). I'd change the 5 to 6 feet distance to 10% of one full wavelength, however. (Your optimum height for the primary antenna is close to 20% (+/- 5%) of one full wavelength.) What you will do is increase the effective radiation upwards. If you are operating at a suitable frequency much of this RF will be reflected downwards providing very good regional coverage. This is a good plan for regional communications, but it would not be expected to increase performance for DX communications.

Certainly adding a second wire below the primary antenna (several % longer than the primary and one full piece) is known to increase signal strength. Some people debate as to the cost vs. dB increase. That part is somewhat subjective, I think. I think of this as a 2-element beam: driven and reflector, which is essentially what is going on.

Cebik has a section on NVIS antennas somewhere on his web site (www.cebik.com) which was informative. As I recall his designs were discussing dipoles, but the general theory would remain the same.

Subject: [SkyWires] Hi everybody-new member from Greece

Dear friends,

I am new member to your group and i am here because of my interest on
antennas.
I want to erect an end fed wire dipole for topband so i think we have
a lot to discuss.
Thank you
Nikos

Hi Nikos:

Your statement, "erect and end fed wire dipole" is a contradiction in terms. A dipole by definition is fed in the middle with one side working against the other. This kind of antenna is a 'balanced' antenna. A loop antenna is another kind of balanced antenna. All other antennas are what are termed 'unbalanced' antennas; they require a ground against which the antenna will work.

An end fed wire antenna is an unbalanced antenna. A common way to configure such an antenna is to choose a convenient location on the ground where the antenna wire will start. This point will also be where your 'antenna ground' starts. Ideally an antenna tuner is placed at this location between the start of the antenna and the start of the 'antenna ground' . If it is not possible to place the tuner at this location then a feed line will have to be provided to connect to the operating position.

Next, the antenna wire is raised vertically from this point as high as possible. The remaining wire is then suspended horizontally. This configuration is called an 'Inverted L' antenna. The length of such an antenna is usually either 1/2 or 1/4 wavelength long. Which one you choose will have implications re: wire length and ground requirements. If you choose 1/2 wavelength then the impedance of the wire at the ground will be quite 'high' ... eg at least several hundred ohms, the antenna current will be low. This means that you can get away with fewer ground radials. If you make the antenna 1/4 wave length long then it will be only 1/2 as long but the impedance will be low and the current higher at the feed point. The good news is that the lower impedance will be easier to couple to a coax feed line, but the bad news is that you will need a more effective radial ground system .... eg more radials.

In your case for top band, the length is usually a deciding factor ... unless of course you have unlimited room. A 1/4 wave end fed wire (inverted L) would be approx. 130' while a 1/2 wave would be almost

270'!! As a consequence many operators use the 130' length with result that they have a 1/2 wave on 80M and 1/4 wave on 160M. Such an antenna is very effective on both bands .... but the ground is critical for 160 effectiveness and coupling is touchy on 80.

If you search the internet for 'Inverted L antenna' and 'antenna ground systems' you will find lots of interesting information RE: ground systems and matching.

Hi Jim,

First,I want to thank you for your reply.
Then i want to mention that when i write for dipole i had in mind the total length of the antenna (L/2) and not the feed point of this antenna (middle,end etc).
My other choice for this antenna (except the inverted L) i think is the windom antenna.
Having in mind that this antenna will be only for topband and not multiband ,and that the TX will be homemade tube linear(with high output impedance)the high impedance of the windom is not problem.
I think i can match the system without a 4:1 balun or something.
For feeder line i think i can use single wire direct to the linear output .
I think for this windom antenna the rf ground or radial system is not critical.
Waiting for your valuable help.

668. 4/1 or 1/1 balun

Yahoo group: SkyWires
Date: 2004-08-16 21:27:21 UTC
From: charles allison
Topic: 668 Message: 668

Hi folks,

I have been subscribed to the list for a while and have up an 80 m loop at the moment along with a pair of g5rv antennas up as inverted vees at 33 ft apex. The primary use of the these antennas is 80 and 40 meter regional traffic net work. The 80 m loop is up about 12-15 feet. It is using a 4/1 voltage balun and is a little bit too long. The wire is 12 awg insulated. At present, the 80m loop is being used only as a receive antenna where it performs at a lower noise than either of the g5rvs, however, the g5rv antennas provide significantly better output signals on both 80 and 40m. An antenna tuner is used. Playing with my new toy, an mfj269, I find the resonance to be in the mid 3mhz area but also, I'm getting resistive component readings of 10-18 ohms inside the shack when near resonance on the various ham bands. The balun is located on one corner of the diamond shaped loop which is slightly longer than wide.

I would like to get this antenna working better for 80/40 m transmission output as well as maintaining the nice quiet receiver input. It would seem that it shouldn't be that hard to outdo a g5rv at 33ft for 80/40/20m. And, if I can't, it would be nice to compliment the g5rv with something that gives us a real alternative for a different pattern.

I currently have a 1/1 current balun I'm thinking of substituting for the 4/1 along with and I also have 450 ladder line which could be used for feedline. With resistance of 10 ohms on 80m, it would seem that things are such that the 1/1 would be better than the 450 ladder line.

I have also been collecting the materials for something like a 160m loop, perhaps in addition to the 80m. I have 33ft pushup poles for doing such a loop but there is a horrific amount of work to clear the brush out of the way to gain access to the area. Besides, I'm not sure how much NVIS propagation I can get from such a loop on 40 or 80m. I've also considered the possibility of keeping the 80m loop at 15 ft and having it towards 1 corner and below the 160m loop at 33 ft.

Anyway, I could use a bit of advice along with some suggestions as to how best to proceed, especially beyond possibly just switching out the baluns.

best regards,

charles

Charles

My advice would be to feed it directly with the ladder line & forget the balun. Use a link coupled tuner like an old Johnson Matchbox. You can homebrew a link coupled tuner for very little $ if you can't find one. I see them on e-bay regularly for around $100. Mine handles 700 watts PEP.

This system will afford you the lowest feedline loss & the widest operating range.

As you know, coax feed has much higher loss than ladder line as SWR on the line increases. This amounts to attenuation of your transmitted signal.

The impedance of the loop will change with operating frequency which makes the effect of your balun a wild card. Get it out of the circuit. The link coupled tuner eliminates the balun from the circuit. They have the added benefit of acting as a bandpass filter on receive.

Regards

Terry

671. SIMPLE ALL BAND HOMEBREW LINK COUPLED TUNER

Yahoo group: SkyWires
Date: 2004-08-19 12:21:35 UTC
From: cpa2000
Topic: 671 Message: 671

This is K1JJ's tuner - his idea & design!

"50 Ohm Unbalanced to Balanced (any impedance) Super Tuner:

It has no balun and power limit is limited only by the diameter of the copper tubing in the main coil.

Circuit is as shown in figure 4 of the PDF file named Open Wire in the Files section of this group.

Use a single capacitor in the output, preferably a >350pf vacuum variable (a vacuum variable cap is nice but any single section 350pf or greater, 4kv or greater bread slicer cap will do. The more power the bigger spacing needed).

Clip tap the capacitor across a 40 turn 3/8" copper tubing, 5" diameter coil. (Home Depot tubing) Mount BOTH capacitor and coil floating above ground.

Then wind five turns of (#14 or greater) teflon wire on the outside of the center of this big coil as an input link. Tie wrap it into place. One end of this link goes to the coax inner conductor and the other end to ground.

The balanced open wire gets tapped on each side of the big coil with BIG clip ons.. Big copper alligator clips work fine...file the openings rounded so that contact with the coil is maximum.

By changing the open wire taps, the capacitor taps and the capacitor tuning you can cover about any impedance or band situation. No switches needed. Use colored tape for each band to pre-mark the tap positions for quick band changes.

A ~1400 pf input tuning cap (large 4 section broadcast receiver type) in series with the link to ground is sometimes used, but I've found it is seldom needed and usually leave it out.

The tuner is simple and effective...and needs only one standard (unbalanced) cap. The rest is easily made."

I think you'll find the loop works well as a NVIS antenna, and more so at the greater height of 33-feet vs. 15-feet. 40 to 50 feet heights have worked very well for me in Missouri.

From: Bryan
Topic: 670 Message: 674

HI All,

after viewing this PDF file I would say this is the most common sense way to approach feeding an antenna of this type.

I have also seen this approach taken for matching antennas of odd impedances on 6M vhf and UP. it works well as there is no balun to choke out signal/ and output power.. even at vhf frequencies where most HF tunner are not capable of going.

There is a copy of such a tuner in the ARRL Antenna Book from 1964 on page 223 << this artical specifically outlines making a tuner for 6meters and one for 2 meters.

Hi ....

I have been using such an antenna as this for ages .... 100 ft long fed with 450 ohm ladder line .... wonderful antenna 80m-10m. On a few occasions I operated on 160m by simply shorting the feed line and feeding the whole thing as a vertical against ground ... again worked just great.

The key to reliable operation with this antenna .... especially if you run any power (100 watts and up) is the antenna tuner .... If you use one of the common unbalanced tuners with a balun on the end I defy you to operate on all bands with a KW. Baluns are simply not the way to go with when dealing with high SWR. In the article a balanced tuner with a link coil is shown. They work well. However they get complicated when you want to quickly switch bands.

I want to put a plug in for another balanced tuner that gets very little press but works wonderfully with this kind of antenna/feed-line system. It is the venerable Z-Match. Do a search on the internet for Z-Match and you will find some excellent articles on how to construct such a device. The only commercial version of this tuner is the KW EZEE-Match .... I see them advertised from time to time on E-Bay. They were made to handle the 100

watt rigs. It would be easy to construct one to handle a KW.

This is a "yes but" type situation.

The 40 meter pattern of a 160 meter loop depends on the loop height, the loop shape, where you feed it and ground conductivity.

I'll make a few assumptions in my answer:
Loop Shape: Square
Loop Height: 60'
Corner fed
Average ground

You should get a pattern of 4 lobes and 4 nulls (think of a 4 leaf clover). Lobes should be off the corners of the loop & nulls should be off the sides. Expect about 10-11 dbi gain off the lobes with nulls down as much as 20dbi.

If the DX station you wish to work is off one of the corners of the loop, you should have a good signal, but, if the station is off a side, a dipole will be much stronger. Take-off angle off the corners will favor DX (ie., low angle radiation).

A low antenna (say 20 feet) will be much less directional & a much poorer DX antenna. Max radiation will go straight up & you'll be left with a cloud warmer.

From: Marc Chappelle
Topic: 679 Message: 681

OK,

I think I should be able to get it about 40 feet up in square or hexagonal configuration.

With all the talk about 160 meter loops, I was wondering if I might want to throw up a loop cut for this band instead of 40 where I plan to spend most of my time.

BTW, I am currently using a 40 meter, ladder-line fed delta loop. I get 1:1 SWR on 40, 20 and 1.3:1 on 17 without a tuner - all the other bands can be tuned with the ATU in my Kenwood TS-2000. Get very good sig reports on 40 from EU and SA, but have yet to work any ZLs, VKs or JAs with it.

Thanks
Marc - KA3ARF

682. 40M loop at QTH

Yahoo group: SkyWires
Date: 2004-08-28 12:44:10 UTC
From: drizzel153
Topic: 682 Message: 682

Hello all. This weekend I plan on constructing a 40M loop at my QTH. Based on my site it will have the following configuration.
Height: 20ft
Perimeter: 120 ft
Shape: rectangle (24x36), actually a diamond with feedpoint and top of diamond along E-W axis. Long segments along N-S axis.
Feedline: 40ft of 450ohm LL to 1:1 Balun to 12' RG-8x (to ATU) as an alternate could use 50ft of RG-8x.

I would like to get some feedback from the group concerning the design. Thanks for your time.

I actually only plan to use this for 20-10m. Thanks again.

I think you need a 4:1 balun.Or better still a 3:1 balun.
Why not use a matching 1/4 wave section of 75 ohm coax connected to
the 50 ohm line?
What say anyone else??

686. 40M loop at QTH

Yahoo group: SkyWires
Date: 2004-08-29 12:54:03 UTC
From: K0PYK
Topic: 682 Message: 686

Give this a try. I built this for 7.070 Mhz and it
works 1-1 on 40 and 2-1 on 20 w/o a tuner. I tried to
put it up as a delta loop, but I could not get the
bottom high enough. It is now just a vertical loop
with 5 sides. I have not noticed any difference in
performance.
Hope this helps.

Thanks for the advise. My rectangle turned out to be more of a parallelogram. However, it works with some RFI. I turn on a touch lamp every time I key down. The ATU makes it work on 20-10m. I seem to have 50% efficiency (as expected) on 15m. Perhaps replacing the 450 ohm LL with 75 ohm coax (23') will keep me from blinking the lamp. Thanks to all.

450-ohm ladder line will not cause RFI if properly installed. Coax is easy to install but will also cause RFI if you do manage to screw the installation up. Ladder line is self-shielding when RF is present because of the balanced RF producing a field around the feed line. This is double the width of the balanced feed line. For 450 ohm Ladder line at 1-inch width means that you should keep any object away from the line by 2 inches at least. When going through a wall the feed line should be 90 degrees to the wall or case with proper feed through insulators. This will ensure a balanced condition on the feed line. It makes no difference if the object near the feed line is a conductor or and insulator. Either one will cause an unbalanced condition. When using balanced feed line both ends of that feed line must have a balanced supply/load condition. This means you must use a Balun between the ladder line and the unbalanced feed line equipment in the shack and the antenna needs to also be balanced. With coax an RF problem is caused by cold soldered joints in the connectors and/or RF traveling down the outside of the coax and the equipment hooked up to it in the shack. Balanced antennas used with unbalanced feed line like coax will have this problem. I personally do not use Balun when running this way at the antenna and coil the coax about 6 inches in diameter with 6 turns to choke off the RF on the outside of the coax to keep it out of the shack. The reason I do this is I might be able to work some one off the coax instead of the antenna where the other station might be in a deep null area of the pattern for that antenna. Keeping the coax, as vertical as possible and at least 1/4 wavelength on the lowest band used will allow your horizontal loop or dipole to also be a vertical for DX contacts as well. This is only for fixed antennas and not for a ratable Yagi or some other type directional antenna. In this case a Balun or some other balanced to unbalanced matching device must be used.

Topic: 682 Message: 690

My 40 meter delta is fed with 450 ohm ladder line that enters the shack via my window. About 2 to 3 inches of the feedline is sandwiched between the aluminum window seal and frame. Is this enough to upset the line's overall balance and adversely affecting the loop's performance? Another 10 feet of feedline actually rests on the tarpaper (nonmetalic) roof. Will this also afect balance?

If the feed line is exactly 90 degrees to the window seal then the balance is ok but you should not have the window seal right on the ladder line! This will attenuate both the received signal and the transmit signal. Same thing with the ladder line laying on the roof material. The window problem is an easy fix. Simply cut a length of wood about 1 inch + or - thick and use some feed through insulators and connect the ladder line to each side. For the roof you can simply use some weights with some fiberglass rods to support the ladder line so it is no closer than 2 inches to the top of the weights. This prevents screwing feed line standoffs into the roof. Just remember, nothing should be closer than 2 inches to the 1-inch wide 450-ohm ladder line. You can also use insulators attached to points of the ladder line to support it with rope. Just make everything balanced. After you fix the ladder line installation you will notice a big improvement.

OK.

I'll get to work on that right away. I had thought about cutting a 2X4 to fit in the bottom of window seal, dril a series of parallel holes in it, run the ladder line through them and seal it all up with silicone sealant. I'll also reposition the loop's apex so that the feedline won't come to rest on the roof, or maybe I'll follow your suggestion and prop it up with sticks or something.

I had no idea that ladder line was so sensitive to object proximity. You say I should hear a noticeable improvement in received and transmitted signal strength? Cool!

Thanks for all your advice Scott

693. Re: [SkyWires] Re: 40M loop at QTH

Yahoo group: SkyWires
Date: 2004-08-31 13:01:41 UTC
From: Scott Erwin
Topic: 682 Message: 693

A 2X4 will work fine but its a little on the thick
side and will be a bit of a problem mounting feed
through insulators. If your not going to run an
amplifier you can cut a peace of Plexiglas and get
some banana jacks from Radio Shack to install in it.
Then just cut a large hole in the 2X4 and attach the
Plexiglas and jacks to that. It would be better to get
the Apex of the antenna higher or moved a little so
the feed line is in the air well away from the roof.
If your going to run power ceramic feed through
insulators are a must!

I thought I might try this:

Drill a suitable hole through the wall directly behind the rig, run a length of coax to the otherside, attach a LDG 4:1 balun to it, then attach the carefully routed feedline to the balun.

Will this method work?

Hi Guys, I've been reading the thread and have something to
contribute.
Don't use steel nuts or bolts anywhere along the feedline. Use BRASS
instead. When RF passes THROUGH a steel circle(nut) it heats the
nut up and power is severly attenuated.
I had a steel nut on a Banana jack and the heat melted the plastic
panel. This heating effect is only apparent at higher power levels
but at QRP levels the RF power is just absorbed by the steel.

From: Scott Erwin
Topic: 682 Message: 696

That will work just fine! I bring my 450 ohm ladder line in through my window as I want a choice on how I want to operate with my equipment. When the amplifier is not going to be used I have a short coax jumper between my transceiver and a 4:1 Balun mounted just below the window. When switching to the amplifier I connect the short coax jumper that is normally connected to the "window " Balun to the input of the amplifier and then connect the short peace of 450 ohm ladder line from the back of my 2 Kw tuner internal 4:1 Balun to the feed through insulators in the window and in the process disconnecting the 4:1 Balun under the window.

Hi Marc,
I have used that method and it worked quite well.
The only difference was, I made my own homebrew balun.

I thought I might try this:

Drill a suitable hole through the wall directly behind the rig, run a
length of coax to the otherside, attach a LDG 4:1 balun to it, then
attach the carefully routed feedline to the balun.

Will this method work?

I have been following the discussion re: routing a balanced 450 ohm ladder line into the operating room.

There are all kinds of balanced lines; 600 ohm open wire line, 450 ohm open ladder line, 300 ohm TV twin lead, 72 ohm line (no longer manufactured ??), zip cord (2 wire extension cord, impedance 100 ohm approximately), telephone outside cable, etc. etc.. They may have different impedance, loss factor, and power handling capabilities, but they all will work as balanced feed lines.

It is possible to splice several pieces of different kind of balanced line between the antenna and the tuner and the performance of the antenna will be virtually the same. For example, if the distance between your antenna and tuner is 75' and you have 40' of 450 ohm line and 35' of 300 ohm TV twin lead, it is possible to splice them end to end. The difference in performance will be negligible. As long as you are not running high power, the 300 ohm line will work fine and the added loss is negligible.

Now if you were to take the same example of a 75' feed line length and you were to make it 74' of 450 ohm ladder line and 1' of zip cord, the result will be the same; there will be negligible loss. So, if your 450 ohm ladder line comes from the antenna to the window of your operating room you can terminate the 450 ohm line at the window, splice in a foot or two of zip cord, pass the zip cord through a 1/4" hole in the window frame etc. and either connect the zip cord to your tuner or to another length of 450 ohm line. I guarantee it will work fine and you will not be able to notice a difference in performance. You may notice that the tuner settings are not exactly the same, but the loss will be negligible and balance will be maintained.

I have used this system for years.

Hi..Just joined the group. I've been looking at the skyloop and
looks like a good candidate for DX.
Was looking at the photos of Art Bell's setup. Is the 350 volts AC
or DC? I assume DC?
I see there is a wind turbine close to the wire. Could that
possiably set a static charge and transfer it to the wire by some
means?? Or possiably the tower is somewhere shorted to the turbine
and or battery storage unit??

All the HF loop Sky wire antennas I have ever put up
when left ungrounded would build up a large static
electric charge after only a few hours. If your
standing on the ground and touch the feed line you
will get a good jolt from it. On my 160-meter loop
after about two hours the end of the feed line brought
close to the ground rod for the shack will produce a
nice blue spark with about a 1-inch gap! My 4:1 Balun
for the antenna provides a nice direct DC ground to my
ground rod just under the window out side and when the
ladder line is disconnected for lighting safety when I
am not operating the station a large jumper wire is
connected to the ceramic feed through insulators where
the 4:1 Balun was connected and the other end of the
jumper wire is connected directly to the ground rod so
the static charge is continually drained off the loop.

Thanks for a bit of practicality regarding antenna
lead-in's.
There are a lot of witches-brew and just plain
pain-in-the-neck stuff regarding antennas in general
and lead-in's in particular.
There is Theory in and for Theory's sake, and then
there is practical implementation... and the two may
never meet.
I've even used TREES as antennas very successfully!!!
A length of random stranded wire ending up with a
brass Eye-Lag-Screw screwed into a tree trunk works
very well as long as your xmitting pwr. isn't too
much. The tree's lattice-work within it's living
cells seem to adapt and resonate together as a cluster
of mini-antennas connected within a 3-dimensional
lattice... much like a large xtal does.
It's just plain fund to push the envelop against
so-called accepted theory, and discover things are not
always as they seem.

703. feeding a 160meter skywire with 450 ohm open

Yahoo group: SkyWires
Date: 2004-09-06 13:14:07 UTC
From: campingfreak2002
Topic: 703 Message: 703

Hello all, I am new to the group here. I am seriously considering putting up a 160 meter skywire myself feeding with 450 ohm ladder line. The information about static build-up that I have been reading on this group was good information but also suspected. Am I to assume that I will gain some vertical component if I keep the feed line straight vertical? Has anyone used a knife switch inline with the feeder to switch between earth ground and the rig? Any ideas would be very helpful.

From: n4zou
Topic: 704 Message: 704

I have a small camper and truck set up as a portable emergency HF station and the biggest headache is antenna setup. I tried mobile antennas first thing with poor results. A 40-meter loop Sky wire worked great except for 80 meters which is required and yes, I did try opening up the loop at the far end and the size is still too big and requires at least three supports. Same thing with a trap dipole, too long and requires three supports even when configured as an inverted "V" antenna. I even tried a Butternut HF6V vertical but I just cant get a proper ground under it using the truck and camper as the ground plane and running radials is out of the question. Most of the time the set up is used in a parking lot and the radial wires will get destroyed in short order. After looking around an old ARRL antenna book and checking the net for information on Magnetic loop's I have decided to build one and try it out. Before I get started on it I would like to have comments from anyone that has built one of these small loop antennas. I already have a nice Jennings Vacuum capacitor rated for 5 to 500 pF and checking it found it to be about 15 to 477 pF. I already have a stepper motor drive system on it, which turns it very slow, and in single steps. It's rated at 5 Kv, which should allow 100 watts without arcing. I have read that the capacitor is the most important part of this antenna. Looking at designs and figuring out the math it looks like I will need 20 feet of 1inch plumbing copper and eight 45-degree fittings to form the loop. This should give me 80 through 20 meter coverage with the loop about 6 feet in diameter which would allow it to lay flat in the truck bed for transport. I also have the ability to install a self supporting 15 foot pole for the loop which should get it in the clear and away from people that could get a nasty burn from the high voltage associated with these type antennas. A site with good information about Magnetic loop antennas is
http://www.iri.tudelft.nl/~geurink/magnloop.htm

From: Scott Erwin
Topic: 703 Message: 705

With a loop using ladder line the ladder line will
become a part of the radiating element when there is a
high current condition at the feed point. This happens
on 80 meters with a 160-meter loop where the length of
the loop is an even harmonic. The feed line becomes a
folded part of the radiating element. If most of that
area of the feed line is vertical then you will have a
distorted pattern with a small vertical pattern as a
part of that distortion.
I would not use a knife switch to disconnect the loop
and ground it. If you did get a direct strike the
lighting would jump the small gap and destroy your
equipment. I remove the ladder line/coax from the wood
board with feed through connectors installed in my
window and then ground them all with a heavy jumper to
the station ground rod and ground system for the house
as per the local code.
"All ground rods for the dwelling shall be
interconnected with at least #10 solid copper wire."

Could some one tell me if a johnson kilowatt matchbox with a missing relay and rear terminal strip will still work ok on my loop antenna?

707. Re: Building a Magnetic loop.(How about a "D")

Yahoo group: SkyWires
Date: 2004-09-07 01:56:47 UTC
From: bambazonke01
Topic: 704 Message: 707

I had a similar setup of a military truck/trailer at one time in the past when I was in uniform. The antenna was a large whip that was mounted on the back bumper and bent over in a "loop" and had the tip connected to the front bumper of the truck through a series variable capacitor. from the ground of the front bumper, a heavy braid ran back to the back bumper where the antenna was mounted. The antenna was connected to the transmitter via a "tuner" that consisted of a parallel tuned circuit with a 2 or 3 turn link coupling to the transmitter output.
In effect this type of antenna is a large 1/2 loop like a "D" on it's back.
You could easily set something similar up and check it's resonance with an antennalizer. That antenna laid down a solid signal all over the continent and the transmitter was only 10 watts AM.
I've been thinking of making something smilar to install in a tent using the fold over tent poles.

709. Hurricane, Loop skywire

Yahoo group: SkyWires
Date: 2004-09-07 11:50:04 UTC
From: rsb3332002
Topic: 709 Message: 709

My 540 foot loop has survived Frances! It is the only antenna left operational right now. Receiving loops, GAP challenger, big homebrew vertical, all down, some in pieces. The beams/ quads were down, and will go back up. The loop is at 60 feet in pecan trees. The trees moved a lot; I estimate gusts at 70 mph. It blew pretty hard for 20-25 hours. This loop skywire is made of stranded copperweld with black tough plastic insulation. I think it is 13#, I bought it from the WIREMAN. There were tons of branches tearing out and onto that wire. Those trees, supporting that wire thrashed around for all that time; did not break it! I supported the loop with five pulleys on flagpole style loops of 1/8" dacron rope, all from the WIREMAN. I might have used cheaper material, but I don't see how it would have held up. Thanks to a generator and this antenna, I never lost communication. Oh, yeah, a big limb,6" or so fell on it and dragged the feed point down on my roof. The feed line is 300 ohm window line, also copperweld stranded same source. I am a happy customer of the WIREMAN, but have no interest in their biz.
Since I have to rebuild all that bigger and better than before, I shall be busy. Fall in Florida is the nicest time for working outdoors, anyway. Nice and breezy!

RG-58 will do fine. On the HF bands the loss in that small coax is so low as to not be noticed even with 100 or more foot runs. If you run an amplifier I would go to a heaver coax as there can be a high voltage or current developed in parts of the feed line and if you just happen to have one right there in your small coax it could burn it. If your running 100 watts or lower you will have no problems.

Shannon:

Glad to hear your loop survived the hurricane. Mine came down during a severe thunderstorm in May (a tree that served as one of the anchors came down) along with five other yagis, quads and wires. I've spent the summer rebuilding them and I'm finally going to get them back up next week. A new tower is replacing the tree as the anchor for that corner, and I'm chomping at the bit to get back on HF on something other than a hamstick or an 10 meter ground plane!

Good luck on your reconstruction project.

712. 4:1 balun great stuff

Yahoo group: SkyWires
Date: 2004-09-08 20:09:47 UTC
From: Bryan
Topic: 712 Message: 712

HI All,

I just finished building the 4:1 balun in the antenna section at:
http://www.wh2t.com/

it cost me zero$ as I had scraps..im sure it would be only a buck
fifty if you had to pay for it..

I actually built two.. one for my loop and one for a future dipole
arangement.

the one on the loop performs great. I was 5x9 in San Antonio Tx on 20
meters sending 50watts.

This device has made all the world of diffrence in how the full wave
160 meter loop couples and performs.

give it a shot and tell me what you think.

I have found the solution! Check the following link.
http://www.qmac.com/Downloads/ML-90%20Brochure%20Web.pdf
This is a PDF file but it's not very big so it downloads well. After doing some research I found that a low loss aluminum or copper ground plane under the loop would improve performance. My small camper has an aluminum roof! A square loop with a circumference of 20 feet with 3/4 copper plumbing pipe would only be 5 feet on each of the four sides and can be mounted on the top of the camper permanently. Simply swing it up vertical for operation. A one-minute job! This would cover 3.5 to 14.35 MHz. No antenna tuner required and just 1 to 2 S-units down from a full size dipole 1/2 wave above ground. I don't think it gets better than this for portable operation. Also the loop bandwidth is very narrow and quiet. Just what you need when operating around other stations transmitting on other bands.

Are you thinking of a DDRR antenna for the camper rooftop?

A DDRR is quite different than a Magnetic loop. The DDRR requires a ground plane under it and connected to it for tuning across a single band. I looked at this design and found it not suitable for my use. It would require large diameter tubing and muffler pipe is suggested as the material to use. It would also mean drilling mounting holes in the top of my camper?.not good! Then the steel muffler pipe flange used for mounting is going to cause a corrosion problem where it's contacting the aluminum roof. The Magnetic loop has the advantage of not needing a ground under it so it could be removed from the top of my camper and used somewhere else. The aluminum ground plane shields the loop from earth losses under it and so performance is improved while operating it close to the ground. Also the square shape is used so it will capacitive couple to the aluminum roof on one side of the loop. The MAG loop can't be used mobile while lying down in the transport position. I plan on using some 2 X 2 pine boards for the mount and looking around the electric fence supplies I found some stand off insulators that clamp to fence posts. These are rated for the high voltages used on an electric fence and will be perfect for use with the MAG loop. I will use two on the bottom side which will allow a hinge type of movement so the MAG loop can swing up and down between transport and operation position and a third one insulating some PVC pipe from the loop holding it up in the operation position.

You are right about the groundplane. The DDRR has to be circular, well not really , it can be oblong. I have seen DDRR's made from RG8 coax that seemed to work well enough but as compared to a 2" diameter pipe it may not have been as great a radiator.
I posted about a "D" bent-over grounded whip recently that also worked extremely well.
From the border between Zambia and Congo I had a great signal into the southern part of South Africa and as far north as Somalia with only 10 watts. Frequency was 8 mhz.The date was about 1961. Check it out. I still have a tuner from that setup in my "use it someday" box. The tuner consists of a roller coil and a single 200 pf variable capacitor. I've seen them quite often at Ham fleamarkets so they may have been used in other equipment as well.

I read your mail to me about that whip turned "D" loop setup. That is what got me to looking around for an easy way to do the same thing and found the site with the luggage rack/MAG loop setup. I almost fell out of my chair when the PDF file finished loading! If I were rich I would just buy one! Being medically retired prevents that and I don't even want to know how much it costs hi hi!
I am about to build a "cheap" loop using RG-8 coax as the main loop element and a stub capacitor made from the same coax instead of a variable capacitor. I will only be able to use the frequency that the stub capacitor will be tuned to and so I will make up several for different bands. This is just to find out if this type antenna will be suitable for use with my setup. If everything works out I will jump in with both feet and build a real MAG loop. Also I am thinking of using copper sheet metal instead of the 3/4-inch plumbing pipe. I have been told that using a flat surface for the loop will improve efficiency on the lower bands. While I was at the sheet metal shop I noticed a machine cutting out shapes in aluminum sheet. It was driven by a CAD program and did a very nice job. I might look into designing a large high voltage butterfly type all copper capacitor for use with MAG loop antennas. I will just need to figure out the cost. Being a machinist many years ago I already know how to build one. I just need to draw up the shapes and get an estimate of the cost of material and machine work.

718. Commercial Balanced Antenna Tuner

Yahoo group: SkyWires
Date: 2004-09-11 08:16:15 UTC
From: Dr.Ace Ratliff
Topic: 718 Message: 718

Hi All,
FYI ,
Palstar is now offering a Commercial Balanced Antenna Tuner BT1500A rated for up to 1500 watts PEP.
At a quick glance the only thing I dislike about it is the variable capacitors rated @ 4.5Kv , I prefer a higher voltage rating.
See it at :

It is rated at 1500 watts PEP so the 4.5 Kv cap is
suitable for the size of the enclosure it's in. A
higher rated capacitor in the same size box would
require a very expensive vacuum variable unit. Also
the inductors are in line. This allows coupling
between them, which degrades performance. They should
be separated on each side of the enclosure.
Considering this is a commercial built tuner with
price a major factor this design is a good compromise.
What I would like to see in tuners with roller
inductors is an optional motor drive. I have arthritis
and I have a serious problem turning knobs. It really
hurts to crank the inductor from 160 to 80 meters on
my Heathkit SA-2060A tuner! I solved the problem with
one of the cheap battery type screwdrivers. I made a
small plastic funnel into a knob adaptor and attached
it to the end of the screwdriver. Now I simply hold
the electric knob turner on the inductor knob and let
it do the work!

I would rather have it in a larger enclosure if it had 6 KV or higher rated caps.
For the price they want, I want higher rated caps.
If you run anywhere near legal limit power it is all to easy to arc the caps especially on 10 and/or 160 meter bands.

From: spark_gap2000
Topic: 706 Message: 729

Oh yeah!!!
The relay and terminal strip had nothing to do with the actual tuner.
They were meant as a built in TR switch for separate transmitter and
receiver.
Don't ever sell this tuner if you don't have to,they are miles better
than anything you can buy today.
Sid.

730. New to group but just in time

Yahoo group: SkyWires
Date: 2004-09-16 17:20:45 UTC
From: Jay
Topic: 730 Message: 730

Hello all
I am putting up a 40-meter delta loop.
The height is 40 ft and the bottom spread will be 50 ft across.
The bottom of the antenna will be aprox 5.5 ft off the ground.
I plan on feeding in the corner.
Currently no amp only an icom746 running 100 watts.
Which 75ohm feed line should I use RG11 or RG59. The 50-ohm is RG312.
The orientation is going to be broadside to the east and west.
Any comments are welcome.

Secondly has any tried to use traps to make the delta loop multi
band. I found an article in the Arrl wire antenna book II.
Looks like a real good idea I was thinking about this for 30 and 20
meters.
Any comments?

Thank you
N3OW
Jay

RG-59 will work fine. The length of the coax transformer for 40 meters will be 234 divided by Frequency in Mhz times .75 will equal length in feet or 24' 6". This will be very close to providing a 1:1 match on 40 meters. Traps are not required for multi band operation even with the 75-ohm coax matching transformer in place and an antenna tuner. You might have trouble with 30 meters. I guess this was the idea behind the added traps and I did try traps on a loop once with very poor results. The part of the loop that should have been removed by the traps still coupled with the part of the loop on the hot side of the traps. If you're going with an antenna with traps just stick with a dipole type antenna. I have found that a lot of ARRL articles on antennas were never really built by the author. They just dreamed it up and published it for the money or to get there name/call in the book.

733. 40m on 160m question...again

Yahoo group: SkyWires
Date: 2004-09-17 04:00:38 UTC
From: johndm90
Topic: 733 Message: 733

This may have been addressed in a previous post and if so, please disregard.
I plan to put up a 160m horizontal loop at approx. 40 ft.
I plan to feed it with coax. I don't plan on using it on 160m but some on 80m and spend most of my time on 40m, and some on 20 and 10 meters.
I'd like to use this loop without a tuner for all bands but I have one if I need to. Do I need a balun at the feedpoint?
Which coax should I use, 50 or 75 ohm and at which frequency do I cut it for...the fundamental freq. of the loop, 1.85 MHz. or 7.250 MHz?
Thanks for your help!
73,
John N5XYO

If your using a modern transceiver you will need an antenna tuner for all band operation. If your using a transceiver with tube finals the Pi network will compensate for the impedance of the loop so just hook it up and go. Most of the time an internal antenna tuner in the transceiver will work just fine with a loop as the SWR will be 3:1 or less on the HF amateur bands. Do not put a Balun of any type at the antenna. You don't need it and most likely will just cause problems. If you're going to put up a 160-meter loop just make the wire length 530 ft long. Do not try and trim the length making it longer or shorter, it won't improve your signal at all. On 80 meters there will be a slight drop in efficiency due to self canceling as it will be operating on an even wavelength but it will still be a better antenna than an 80 meter dipole less than 1/2 wavelength above ground. On 40 meters it will have four major gain lobes and is a very good antenna for working DX and local stations. On the higher bands of 20, 15, and 10 meters DX stations are easy to work with very pronounced gain lobes and low angle radiation.

Go to your local building supply store and buy the
required length of wire you will need. Insulated 16 or
14 gage stranded will work fine. A length of 1 inch
PVC pipe for making the center insulator and support
insulators. You might like the insulators used with
electric fence so check the electric fence supply
area. Most of the antenna supply people use these
insulators in there antenna projects and you can buy a
whole bag of them for what the antenna supply guys get
for two!

740. New t the group. 160 meter loop

Yahoo group: SkyWires
Date: 2004-09-18 00:28:48 UTC
From: kb2sdrjay
Topic: 740 Message: 740

Hello,

I am new to the group and would like to put a 160 meter loop up at my QTH in SD, when I move there. I would like to support it by 4 Electric poles, I would like to get 40 foot poles to support it or taller. My questions are, will 4 poles be enough to support the antenna??? What is the recommended way to build the antenna? What am I to expect as far as performance???

743. Revisit of old question?

Yahoo group: SkyWires
Date: 2004-09-18 14:37:26 UTC
From: Dan Gilliam
Topic: 743 Message: 743

I seem to find that the question of SkyWire Loops is like the chicken and the egg. More opinion than answers.

I need answers BEFORE I put up my antenna. I live in the woods and I have lots of trees that would support a system about 30 feet high, as long as it is counterweighted. Lots of wind.

My problem is here:

I used EZNEC ARRL version to analyze my plans. IF (note the caps on IF)I am using it right, and I design an antenna that works great at 1.9 MHz, the SWR will be GREAT with a 512 foot loop at 30-35 feet. But it would seem that 80m, 40m etc. are off the scale for SWR.

I do not have an antenna analyzer and have not yet strung the trees full of jacketed copper. For some of you with all of your marbles still in place, this is likely a simple thing. I seem to find a blockage between my ears when it comes to using this program to build a multiband antenna.

ARRL handbook for 1994 had an article that said to just throw wire up and feed it just off of a corner with coax, skip the balun and it will work fine. I have seen so many other articles that nixed the idea.

Someone here has experience with this. Please share what you think I am doing wrong.

Thanks in advance.
Dan KE4PDO

744. Re: [SkyWires] Revisit of old question?

Yahoo group: SkyWires

From: David Shrum
Topic: 743 Message: 744

Dan I can only relate my experience with my approximate 530 ft. (1.9 MHz) loop. Mine does not tune in ANYWHERE below 3.1 SWR. My loop is easier to tune from 40 Meter and up (with my older MFJ Tuner II (MFJ-944)). Although it seems to work work well on 160 & 80 and all the rest of the bands, if I were to know what I know about my experience with my loop, I don't think I would put up a loop, I would stick with dipoles. Although the fact that my loop is not supported from the trees, but against the trees, trunks and what-ever it can hang from probably has a big effect on my loop.

This again is MY experience and according to most all other reports people have excellent results with theirs.

Since there seems to be no "standard" way to put up a loop, what you'll get are mostly opinions. The factors are - in no particular order - height, shape, length, feedline, tuners, desired bands for operation, etc.

I think that nearly every one of these factors has been debated on and off on this list.

So here's my opinion(s): Run a shorter loop (40m, about 130 feet) with less expensive wire - a 530' loop is a MAJOR undertaking. Feed it with window line (450 ohm), or even with 300 ohm TV lead like I do. And use a tuner - most modern rigs have them built in, or if you're running a fossil rig like me, lots of outboard tuners are around.

And play with it. I run on 160 through 10 on my 40m loop, and get out all over the place. It's on a little suburban lot about 18' above grade... the program says it should be a dud but it's the best antenna system I've ever had.

So - there's my opinion. Start small and work your way up.

Have fun & good luck!!
73,
Jim

You might try changing your feed line length. Cut a foot or two and try it again. You can also add a foot or two if you're already at the minimum feed line length with your setup. The loop is not an exact 50-ohm match if your running coax so the impedance at the transceiver will be different all along the length of the line. Same thing with ladder line. Some places it will be good and some places it will be hard to match. If you take the time to try it you will find a feed line length that will work fine for your installation.

747. Angle aluminum for Magloop element.

Yahoo group: SkyWires
Date: 2004-09-19 23:42:14 UTC
From: n4zou
Topic: 747 Message: 747

I have a test Magloop built with RG-8 coax as the element and performance is outstanding considering the size and height above ground. One thing I ran into was trying to make the loop operate on 20 through 75-meter bands. The element is too small on 75 meters and almost too big on 20 meters. I have figured out that two Magloop's are required. One for 40 and 75 meters and one for 20 through 10 meters. The 40/75 Magloop will be made from 1 inch copper plumbing pipe and will be 9 feet across each of the four sides. This can be transported on the side of my camper. For the 20 through 10-meter loop I already have some 1-inch aluminum angle and I am considering making it out of this material. The program I downloaded for design of Magloop antennas only deals with round and flat material. I was just wondering if anyone has a formula for converting the area of angle material compared to round. Flat is width divided by 2 for the round material formula. I would guess that it comes out the same as round tubing but I am just guessing!

HI Dan,

Its late here but , here goes,
I have a 500+ft loop about an average of 15-20 ft off the ground..
sort of a rectangle shape I think.

initally I had all kind of problems.. I was feeding with 450 ohm
ladder line. and then a piece of RG8 into the shack.. the SWR was
aweful. I could get it down with a tuner on all bands but 160, it
was still TOUCHY at best.. some good signal reports on the High
bands , but equal as many poor ones on 40,80,and 160.

I went to www.wh2t.com DR Ace's site.. I built his open core balun,
(some call it a transformer) no ferrite core here!.
low and behold.. I was getting much better signal reports on low
bands and also much more distance as well. the balun is in the
ANTENNA section of the Wh2t site. It is very inexpensive to
construct. I built mine in about 35 minutes , out of spare items in
the basement shop.. basically cost me nothing in $$$.

I have had many NEGATIVE REBUKES for calling this a balun and on and
on. but "the PROOF is in the Pudding" so they say!. I cooked the
Pudding and wow what a difference.
I dont own a antenna analyzer of any fancy equipment, IM a disabled
operator on a tight budget! Dont ask me all the 411 on the ratios
and exact impedance, I simply have nothing to tell you, except it
really helped a lot.

I am running about 30 ft of 450 ladder line, and about 15-20 ft of
RG-8U coax. I installed the wh2t balun in between the ladder line
and coax and then wrapped the connections with electrical tape. I
also grounded it to my earth ground OUTSIDE the shack. my only final
tips is to ORIENT the balun in such a way that the water doesn't
collect in any way inside the PVC tube or in the connections. I
tinned all the wires in the house with my electric solder iron,
then proceeded outside with my hand held propane torch with
soldering tip. it worked like a charm, FAST AND EASY flow!

please tell me if you build this and let us know your results.

just as an FYI I have the MFJ 934 tuner and an ft840 barefoot,with a
stock hand mic.

Good luck Bryan Kc8hps

Hi Keith:

The link style tuner is excellent for matching a balanced feedline/antenna. However, the switching arrangement used in the Johnson Match-Box is very complicated and demanding of the switch quality. As you can see the switch contacts in some cases can be handling considerable voltage. Multi-wafer - multi-position high power ceramic switches are hard to come by.

In Match-Box 'days', another method of mult-band tuner construction was to use 'plug-in' inductors complete with the link coil for each band. I used this method years ago .... as a result the tuner inductors were fully exposed and I had several plug-in's, one for each band of interest. The wonder of the Match-Box was that it allowed the whole unit to be enclosed in a metal box and inductor changes were accomplished with a front panel switch. They were very expensive.

Then, for many reasons, the balanced feedline/tuner arrangement fell out of favor and the for the most part the balanced antenna tuner was no longer manufactured. However, the only commercial unit I know that continued with the link coupled antenna tuner was a British Company (now defunct I believe). Their antenna tuner survived because it was efficient, non band switching, covered all Ham bands, and would handle a either a balanced line or coax. It was called the KW E-ZEE Match. I still see them for sale on E-Bay.

If you search the Internet you can find several articles dealing with the KW E-ZEE Match. This tuner is designed for the 100 W output level. However, the circuit arrangement (Z-Match) is simplicity itself and a more robust multi-band tuner is easy to construct. I have used such a tuner for many years and I can attest to it's efficiency and ease of use. It works equally well whether the feedline is coax or balanced line such as 450 ohm ladderline or 300 ohm TV twin lead etc...

You can check out the following site for a lot of information on the operation and construction of such a tuner. I highly recommend it.

I would guess that 1" angle stock would be equivalent to 2" flat
material. I wouldn't think the 'L' shape would affect the inductive
characteristics .... it would of course double the surface area.

Just because it does not have a ferrite core does not mean that it's not a Balun! My 4:1 Balun has no ferrite core either and it works great. It's an AirDux made with two #B2009 coils. It's the same thing as the old Heathkit remote mount Balun in a box. If you want to get technical about it you really need a 9:1 Balun but for a Loop 4:1 works just fine!

752. Antenna Question

Yahoo group: SkyWires
Date: 2004-09-20 15:07:02 UTC
From: Rtnmi
Topic: 752 Message: 752

I have some scrap laying around and wanted to build a dipole antenna or a single band vertical limited space antenna. Here is what I have available:
abt 50' RG6 75 ohm
abt 50' RG59 75 ohm
abt 88' Orange Insulated 6 conductor telephone wire
1 aluminum extendable paint roller rod abt 13' long
1 old circuit board abt 6"X6" for insulator(s)
abt 300' nylon rope.
some 1" OD PVC abt 15'
No ladderline
No flat lead tv line

Any ideas how I can use this most efficiently for building an antenna that I can tune to the cw portion of some hf band(s)? I have no antenna tuner so I need to make it as wide banded as possible.

God Bless and be encouraged,

That's what I was thinking so it would be the same as
using 1 inch aluminum tubing. I know using aluminum
will drop the efficiency of the loop slightly but
adding the extra 1-foot length over 10 feet takes care
of that. Using aluminum makes the loop so light and
manageable for portable operation in a parking lot
where you can't have wire antennas strung in trees,
which are not there!

Hi Rev.

Your post is really interesting .... it sounds almost like a group workshop exercise designed to promote interaction. I'm willing to bite. First, the most important information is antenna support and you make no mention of it. I am just going to have to assume there is a tree, a roof gable, or some such structures available to hold up the antenna. I will assume you have a house with a side drive and a gable roof.

You have 100' of 72 ohm coax; good we have established the feedline.

The type of antenna? I prefer the dipole in this situation since it will be much easier to create an efficient antenna than with a vertical, given the materials you list. The efficiency of a vertical will be directly related to the ground system, radials etc., while the dipole efficiency will be related to achieving height.

The wire you mention is not your usual antenna wire .... the 6 conductor telephone wire. However, it will have some advantage. It will consist of 6 thin wires #20 ? all wrapped in a plastic sheath. When you cut a length for a dipole element you will solder all six wires together at each end leaving at least 6" extra. Tape up one end and then simply bend the ends into a loop and secure the loop with tape. You will now have an element

made of 6 parallel insulated wires with a loop at each end to which you can attach a rope etc.

You mention you have 88' of this telephone wire .... that means you can choose a band as low as 40M (approx. 66'). My favorite band is 20M which would have a dipole length of approx. 34' (each element would be 17'). At this point you can see I am discussing a single band antenna. A mult-band antenna with no tuner and the materials you outline is too complicated.

Let's assume you choose 20M. check the dipole formulae to be sure of the total length and say it comes to 34'. You will need 2 elements 17' each. allow at least 6" extra at each end. Strip all 6 wires at each end and solder them together. Seal the soldered wires at one end. Form a loop at each end and secure it with tape. You will now have 2 elements each 17' long with loops at each end. One end will be sealed and the other will have the soldered wires exposed.

Now, a dipole is a balanced antenna and coax is an unbalanced feedline. The impedance match will be good but you really need a device to couple the balanced antenna to the unbalanced feed line. I suggest a 1:1 balun formed by coiling the coax at the feed point. Here, cut about 1 1/2' of your 1" pvc. The top of the pipe will be where the exposed ends of your 2 dipole elements are fastened. EG wrap the element ends around and fasten in place with small plastic tie wraps through small drilled holes in the PVC pipe. Form one end of the coax so you have 2 leads of sufficient length to reach the antenna elements ... 6" ??. tape or fasten the coax near the top of this piece of PVC. then coil about 20 turns or more on the PVC then tape for fasten the coax to the PVC at the end of this coil. This is your 1:1 balun. The other end of the coax (connected end to end as required) will go down to your operating position.

I don't know exactly what your 13' paint roller handle looks like .... but I suggest fastening it in some way to your high spot .... lets say you have a gable roof. Eg. a couple of screw clamps ?? Or fasten to your chimney etc... In any event you have this extendable handle fastened on the roof. Now with some electrical tie wraps fasten the 1 1/2' PVC pipe (which is the center of the dipole and is the form on which you wound the balun) to the top portion of the paint roller handle. Now extend the paint handle to full length and maximum height for the center of the dipole. Tie appropriate lengths of rope to the loops formed in the ends of the dipole elements and tie them off such that you are forming a kind of 'inverted V'.

This center of this antenna would be at least 8' over the peak of a single story house for a total of about 18' to 20' above ground. Keep the ends of the dipole at least 8' from the ground. This antenna will be very efficient, represent an excellent match, and maintain antenna balance. You will make many many contacts.

If you have a tree .... simply hoist the center with your rope ..... remember higher the better .... anything 20' or more will giver solid performance. There! How did I do?

PS .... don't throw the circuit board away.

Hello Jim:

Thanks for the reply. You did *real good* HIHI .

The only place you left me was when you got to the Balun thing.

#1 I was told it had to be more complicated to do a Balun and that it had to be 9:1 preferably or at least 4:1.
#2 The reason you left me is that I have never *really* understood the whole theory behind the Balun thing.

Oh yes I have read the theory until I was blue in the face, but there is usually a practical tie in that is missing when I don't get something like I don't get Balun. Problem with me is if I don't get the theory I always have a hard time putting it to practice.

By the way I just got this morning from a friend of mine an old radio shack type 20' telescoping antenna mast the kind with the guy wire ring around it (which it has) and an old rotted spool of 72 ohm coax (the coax is in *very* good shape just the wood is badly weathered) and 7 sections of 20 foot 2 inch galvanized steel where each section can be inserted into the other. (kind of thin for 140' but might work for 40 if I mount them to the ends of the mobile home. (double wide 36' long) No on second thought I guess that is too short. Well maybe I could mount one of them and do an inverted V. I just don't know which is going to be better the inverted V or a straight dipole.

He also had in a junk pile near his dumpster a roll of about 100' of 12AWG Electrical wire. Now I have *allot* more coax to work with about another 200 feet. The only problem is that I don't have a tuner and it is 72 ohm cable. Can I make the whole thing out of the 72 ohm coax or would the shield block the center conductor from radiating?

Any further ideas and a more detailed explanation of the Balun concept would be *MOST* appreciated. You sound like someone who just might be able to get through to me the way you explain things is excellent.

Now, a dipole is a balanced antenna and coax is an unbalanced feedline. The impedance match will be good but you really need a device to couple the balanced antenna to the unbalanced feed line. I suggest a 1:1 balun formed by coiling the coax at the feed point. Here, cut about 1 1/2' of your 1" pvc. The top of the pipe will be where the exposed ends of your 2 dipole elements are fastened. EG wrap the element ends around and fasten in place with small plastic tie wraps through small drilled holes in the PVC pipe. Form one end of the coax so you have 2 leads of sufficient length to reach the antenna elements ... 6" ??. tape or fasten the coax near the top of this piece of PVC. then coil about 20

turns or more on the PVC then tape for fasten the coax to the PVC at the end of this coil. This is your 1:1 balun. The other end of the coax (connected end to end as required) will go down to your operating position.

I don't know exactly what your 13' paint roller handle looks like .... but I suggest fastening it in some way to your high spot .... lets say you have a gable roof. Eg. a couple of screw clamps ?? Or fasten to your chimney etc... In any event you have this extendable handle fastened on the roof. Now with some electrical tie wraps fasten the 1 1/2' PVC pipe (which is the center of the dipole and is the form on which you wound the balun) to the top portion of the paint roller handle. Now extend the paint handle to full length and maximum height for the center of the dipole. Tie appropriate lengths of rope to the loops formed in the ends of the dipole elements and tie them off such that you are forming a kind of 'inverted V'.

This center of this antenna would be at least 8' over the peak of a single story house for a total of about 18' to 20' above ground. Keep the ends of the dipole at least 8' from the ground. This antenna will be very efficient, represent an excellent match, and maintain antenna balance. You will make many many contacts.

If you have a tree .... simply hoist the center with your rope ..... remember higher the better .... anything 20' or more will giver solid performance. There! How did I do?

PS .... don't throw the circuit board away.

756. Omni Loop Antenna - HF Antennas - Products

FO&A,

HF Antennas - Products

HFA=> http://www.hfantennas.com/products.htm

Click-On the "Omni Loop" Antenna

* 160-10 Meters @ 560 Ft. [140 Ft Sq]

* 80-10 Meters @ 290 Ft. [73 Ft Sq]

* 40-10 Meters @ 145 Ft. [36 Ft Sq]

Omni Loop come as a "KIT" Complete with pre-measured
insulated Q-Flex wire, connectors, Loop Balun, sliding
tensioning insulators, and instructions, including
figure-8 folding. If your installation will not require
the loop to go through pulleys or around, over, or through
trees or other obstacles, we will assemble it free of charge.
Otherwise, take it in standard kit form so you can thread
it through, around or over the obstructions before attaching
the feedpoint.

Feed Line W/Pl-259's
FL98 - 98 Feet 1KW
FL50 - 50 Feet 1KW

Hi:

#1. The impedance of a resonant dipole is approx. 72 ohms .... changes a little when you slope the ends in an inverted V ... but not enough to worry about. The impedance of your coax. is also approx. 72 ohms. Therefore, the balun needs to be 1:1. #2. If you made the dipole out of 300 twin lead (what is called a folded dipole) the feed point impedance changes to approx. 300 ohms. Therefore, a balun needs to match 300:72 or approx. 4:1. If for whatever reason you designed an antenna that represented a feed impedance of 650 ohms then you would need a 9:1 impedance transformation, eg 650:72.

However, a balun performs 2 functions. It can provide impedance transformation ... example #2 above 4:1 .... but more importantly it provides 'balanced' to 'unbalanced' transformation. Coax. requires RF currents to be within the cable, between the inside of the shield and the center conductor. When you connect the shield to one side of dipole and the center conductor to the other side of the dipole the impedance match is correct (no impedance transformation is required) but antenna current now flows on the outside of the coax and it becomes part of the antenna. It becomes funny looking twin lead.

The simplest way to stop antenna currents on the outside of the coax is to form the coax into a coil immediately at the feed point. EG it forms an RF resistance on the outside of the shield or a 'choke'. So if you wind a coil of coax on your PVC pipe approx. 8"-12" long you will choke off most of the antenna currents on the outside of the coax. This is the reason you want to bring the coax away from the dipole in a perpendicular direction. You want it to be equal distance from either side of the dipole

so the induced currents from the radiating dipole elements will cancel themselves out.

This is a simple and effective BALanced to UNbalanced method or device ... referred to as a BALUN. This method does not use a toroid core.

One of my favorite antennas is a 100' inverted V with the apex 30' up supported by telescoping lengths of galvanized steel pipe. In one arrangement (when I was also living in a mobile home) was to erect the pipe with 3 equally spaced guys at the top and staked out in the lawn. 2 guys were the radiating elements and the 3rd was thin rope. I fed the dipole in the center with 300 TV twin lead to an antenna tuner. This antenna works even better if the base of the 30' pipe can be placed on the roof. I once had this arrangement on the peak of a 2 story house .... great antenna! In this arrangement the top of the pipe was about 70-75' above ground and my shack was in the basement. It was truly an all band antenna ... on 160 I treated the whole thing as a vertical (75' of twin lead) and the 100' inverted V became a capacity hat .... and used the hot water heating pipes as ground. It was a really good antenna for 160M.

In your case you would use dipole wires cut to the band of your choice and feed it with the coax choke (BALUN) ... clamp the PVC BALUN to the top and simply tape the coax down the pipe. If you can get 40' up all the better. the steel pipe will hold up well but needs to be guy'd. Your dipole will already provide 2 guys. If you brace the pole against the mobile home you should be able to get away with one set at the top.

I found the inverted V to be an excellent performer. The largest antenna currents are found closest to the feed point (at the center) of the dipole. Just make the apex angle as large as possible by tieing off the ends as far away as possible.

758. Any Good Schematics for 160 meter Loop???

Yahoo group: SkyWires
Date: 2004-09-21 16:06:38 UTC
From: kd5srl
Topic: 758 Message: 758

I recently purchased the ARRL Antenna book to get a basic understanding of antenna(s). As I can fully admit I'm new to ham and new to antenna building. What I would like to do is build a 160 meter loop that booms and I've come to a cross road now that I've been reading in this wonderful group. I read balum / no balum, 1:1 / 4:1, ladder line -vs- coax for feed and combinations of the two.

What I need is the simple honest plan of a working 160 meter full wave loop... one that is not just a plan but one that is and has worked. One of the things that got me interested in amateur radio was the desire to build and tweek an antenna, knowing... hey I built that. Any hep will be greatly appreciated. Yes I'm new to the group so if this is a redundant question, I'm sorry.

Best 73s,
Paul

I like this question. I agree with the motivation of ham radio. I also love working with antennas (NOW) HIHI :0)

I think I have the balun question under control now also.

The only question I have now is can the dipole be made from *only* coax and bypass the balun all together?

KD5SRL,
I've not had a lot of time to build my skywire loop antenna for 160, but over the past two weekends I have placed over 500 foot of wire in my back field as an almost loop. I only got 2 corners above 20 foot. The other two corners are in some trees as high as I could reach. I am feeding the loop with some spliced together twinlead.

I too am new, I've only been licensed a little over a year now. I've heard the arguments balun/no balun and coax/ladder line. I went with what I had at hand. I've basically have a rectangle sloping downard on one side. The wire is zipcord and I'm feeding it with twinlead from radio shack. I've not had time to test it yet, so it may not actually work :) I was on 160 last night and heard a few stations,and can even get a low swr on most of the 160 band, but when I had time to actually test it everyone was gone. I will let you know how it works when I get time to call more CQ's...

The answer is yes .... there is a version of the dipole that utilizes 72 ohm coax for both the dipole elements and the feed line. It is often configured in the inverted V arrangement. It does not require a balun in order to maintain balance or impedance match. It is claimed that this type of antenna is broader than a standard dipole and will give an acceptably low SWR across the whole band.

This antenna is a bit more complicated and you need to take care in preparing the coax elements. The antenna is known by the name "Double Bazooka". There is an excellent description of how to prepare the coax for this type of antenna at "Dr. Ace's" Web Page at the following location.

http://www.bloomington.in.us/~wh2t/bazooka.html

Hi Paul,
Before I attempt to answer your question(s).
Let me ask you,
Do you intend to use the antenna only on the 160 mtr band, or multi band ?
Do you have an antenna tuner aka matchbox ?

Ace,

Thanks for the quick reply! What I'm looking to build is 160 meter full wave, multi-band: 160, 80, 40, 20 & 10 if possible. Yes I have LDG AT-1000 1kw autotuner to match with a Kenwood TS-2000. I have a Amaritron AL-811H to drive a few extra watts if needed.

At this point I'm working with an Alpha Delta DXLB Plus with the feed point about 40 ft up. My property is on a hillside at approx. 30 deg. on 1.5 acres of forrest. I'm not getting good reports without use of the power amp. I've been told my signal on 80 meters is weak when barefoot, using phone, good signal reports... on CW of course. I want a nice antenna (loop) that will BOOM! It would be nice also if it were clean & quiet as I've heard loops are over dipoles. Can you help me out with this one? It would be appreciated.

I have 500' of #12 insulated solid copper wire, 200' of RG-213 and a CAL-AV Labs 1:1 Balum.

Best 73s,

Paul - KD5SRL

765. 160 meter loop on 40

Yahoo group: SkyWires
Date: 2004-09-21 18:27:43 UTC
From: tukatuk4
Topic: 679 Message: 765

Hi all
I just love my loop.... This thing rip's up the band
on 40.. I work so many stations my voice is almost gone.
If you have the room for a 160 meter loop that is the way to go.

Mark K6fej

HI Rev
Well the loop here is 528 feet of #14 up about 50 feet,
I am feeding it with 75 feet of 450 ohm ladder line.
The match is good on 160 however I use a Palstar AT4K
balanced tuner to cover the rest of the bands and widen out
160. The palstar is great low loss tuner. Qst just did a review.
My experience with the loop has been great... Low noise is a
big plus.. I used a sling shot and fishing line to get it up
in the trees. It really is a great low cost antenna. Now I want to
make a bigger one :-)
73 and good DX Mark K6fej

Hi Paul,
I recommend about a 530 foot horizontal loop (if you can come up with 30 more feet of wire).
Feed it with the length of RG-213 needed to reach the station , no balun.
Use the LDG AT-1000 1kw autotuner and you should be able to work 10 - 160 meters , No Problem !

There are other ways it can be done, This way will work great.

Subject: [SkyWires] Re: Any Good Schematics for 160 meter Loop???

Ace,

Thanks for the quick reply! What I'm looking to build is 160 meter full wave, multi-band: 160, 80, 40, 20 & 10 if possible. Yes I have LDG AT-1000 1kw autotuner to match with a Kenwood TS-2000. I have a Amaritron AL-811H to drive a few extra watts if needed.

At this point I'm working with an Alpha Delta DXLB Plus with the feed point about 40 ft up. My property is on a hillside at approx. 30 deg. on 1.5 acres of forrest. I'm not getting good reports without use of the power amp. I've been told my signal on 80 meters is weak when barefoot, using phone, good signal reports... on CW of course. I want a nice antenna (loop) that will BOOM! It would be nice also if it were clean & quiet as I've heard loops are over dipoles. Can you help me out with this one? It would be appreciated.

I have 500' of #12 insulated solid copper wire, 200' of RG-213 and a CAL-AV Labs 1:1 Balum.

Best 73s,

Paul - KD5SRL

Ace,

Thanks for the information. As soon as I get it built and tested
I'll give you an update. BTW... nice web site with great information
you have.

Best of 73,
Paul

Now I did it. Trying to make the Bazooka, out of habit, I cut the coax in half. If I solder the center conductors back together and insulate them from the shield at the middle, can I still go on as though nothing ever happened?

I think I have the balun question under control now also.

The only question I have now is can the dipole be made from *only* coax and
bypass the balun all together?

The answer is yes .... there is a version of the dipole that utilizes 72 ohm coax for both the dipole elements and the feed line. It is often configured in the inverted V arrangement. It does not require a balun in order to maintain balance or impedance match. It is claimed that this type of antenna is broader than a standard dipole and will give an acceptably low SWR across the whole band.

This antenna is a bit more complicated and you need to take care in preparing the coax elements. The antenna is known by the name "Double Bazooka". There is an excellent description of how to prepare the coax for this type of antenna at "Dr. Ace's" Web Page at the following location.

Thank you Jim:

I have the coax together and I have made the balun, now I am working on the circuit board to mount everything to. I hope to have everything ready by this weekend to put on the poles. I now have the telescoping 20 foot mast from radio shack and also 7 20 sections of galvanized steel posts as well. This may turn out well after all. I am excited (as only another ham could understand). No one seems to understand why Dad is so excited over a "bunch of wires and poles). Well we do don't we HI HI :0) They are about to find out just how exciting it can be, once I get everything in place.

Yahoo! Groups Links

774. New link. Loop calculator.

Yahoo group: SkyWires
Date: 2004-09-24 13:29:22 UTC
From: n4zou
Topic: 774 Message: 774

http://ka1fsb.home.att.net/loopcalc.html

The above link which I added to the Links area for the group has a simple calculator which uses the standard formula for determining the total wire length for a single element, full wave loop antenna, (1005/MHz). It also calculates measurements for:

A square or diamond loop shape

A rectangular shape with a 2:1 ratio, (where the horizontal is longer than the vertical length by a factor of 2)

A delta or triangular loop shape

A circular shape

in the HF and VHF Amateur Radio bands.

775. RE: [SkyWires] Antenna Question

Yahoo group: SkyWires
Date: 2004-09-25 16:02:49 UTC
From: Rtnmi
Topic: 752 Message: 775

I have question for anyone who is knowledgeable and willing to answer it.

When we connect a feedline to an antenna - are we making a parallel or a series circuit with regards to reactance?

In other words if I connect a 50 ohm feedline to a 300 ohm dipole without any matching circuit what impedance does my transmitter see. A series or a parallel circuit?

Also if I connect a 50 ohm feed line directly to a 75 ohm feed line say with a barrel connector. Have I made a series circuit or a parallel circuit or is it neither?

If I connect a 50 ohm feedline to a 75 ohm feedline and then to a 300 ohm twin lead but the 50 ohm feedline is 50' long the 75ohm line is 10' ling and the 300ohm twin lead is 25 feet long. Do the lengths affect the impedance or does is matter? What impedance would my transmitter see?

The last question is -- can I make a loop antenna that will fit on my roof - (say for 160 Mtrs) by measuring the length for a half wave length and wrapping the loop with multiple turns therefore - simply increasing the number of turns and decreasing the physical size and still end up with an efficient antenna?

Tnx,
Robert

776. Re: Antenna Question

Yahoo group: SkyWires

From: bambazonke01
Topic: 752 Message: 776

Robert,
I'll try to answersome of your questions.
If you look at coax in an analytical manner with respect to inductance and capacitance then the center conductor can be drawn as a string of series inductors with small capacitance to the shield along the whole length.
If you draw a inductor with a capacitor to ground at each end (like a Pye circuit) then it can be redrawn as a PARALLEL circuit. So then the coax as a whole can be drawn as a parallel circuit.
When you connect to a dipole the top of the coax it is drawn as a SERIES circuit. Draw it out.
For Connecting a 50 ohm coax to a 300 ohm dipole you would calculate Z = square root(z1 +z2) (I think):-)

With regard to the rest of your question on the multiple lengths of different feedlines, the Z will alter dependant on frequency. That is why you can add or subtract a short length and change the feedpoint impedance.
Remember, the impedance of an antenna is reflected at every 1/2 wavelength of coax. If the impedances are the same (ie.50 ohms for antenna and coax) then it doesn't matter on the length.
If the impedances are different you need to make adjustment to get a match to the transmitter output.
I hope I have shed some light on this difficult question and I'm sure some other guys will now add their comments.

779. A feedline experiment...

Yahoo group: SkyWires
Date: 2004-09-26 22:46:57 UTC
From: JimMcSkate@aol.com
Topic: 779 Message: 779

First, the background: I run a 40m skywire loop fed with 300-ohm TV twinlead - fine for the 80 or so watts I run on my old Kenwood TS-820.

I tune the loop with a manual, non-balanced antenna tuner - a Kenwood AT200. It does have a "random wire" output, and that's what I use to drive ONE LEG of the feedline; the other leg is grounded at the tuner, OR is left to float open. (I tried a ferrite toroidal balun, but it was a turkey, so we'll leave that one out of this.)

I had posted a simple description of this a week or two ago... and I received a private response from Jim, VE3DDY. He's hit upon a truly original idea - that instead of grounding the "grounded" feedline leg, I put a variable capacitor in series - then I *could* use the cap to "steer" the pattern of the antenna around. I am able to do this experiment, but the most "science" I can muster is cut and try... I don't have a reliable method (or assistants) to take field-strength meter readings, and it's not likely that I can devote sufficient time to it. But it's an experiment others can try as well - and I wanted to share Jim's email with the whole list in case others want to try it. I will report my own results when I have stuff to report...

73, Jim WA2LGN

<snip>

Hi Jim,
Interesting feed on your loop.
Feeding it with one leg of the twinlead grounded makes the twinlead a part of the radiator as current flow must then be a MAXIMUM at the ground point .
Several years ago when I was in the military I was a radio technician. One of the "loops" I serviced was on a vehicle and consisted of a 25 ft whip that was mounted on a truck's rear bumber. The tip of the whip was bent over in a big arc and grounded to the front bumper through a capacitor. The capacitor was in series but in effect the tip was grounded. A large copper braid ground strap went from the front bumper back to the rear bumper where the feed poit was.
I think the idea of grounding the tip through a capacitor was to force the current loop further up the whip. Anyhow the antenna worked gang busters and I used to lay a potent signal down all over the continent (Africa) with only 10 watts on 8 mhz. Later on when I got a 10 watt SSB set I used to keep regular skeds with United Nations forces at Ishmalia on the Suez canal . My location then was in the northern part of Zimbabwe.
I've often thought of building one of those loops.
The reason for this ramble is I wonder what would happen if you put a 150 pf variable capacitor in series with the grounded end of your loop? Possibly by changing the position of current loops on your sky wire you could "steer"
Ideas breed ideas the signal like you do with a beam.

If you take two pieces of equal lengths of coax, lay them side by side and solder the shields together at both ends. Then use the two center conductors as though they were twin lead or ladder line. This raises the impedance value of the line to exactly double its original value. If you use two pieces of 50 ohm coax then you have a near perfect match to a full wave loop antenna at the fundamental frequency!

If you move up to harmonic frequencies, then this no longer applies since the 100 - 104 ohms of the coax is only good for the design (lowest useable) frequency. And, your coax is impervious to nearby metal objects such as gutters, aluminum siding etc.

You still need a tuner between your 50 Ohm transmitter and your "shielded twin lead" feed line for multi-band operation.

What Jim, VE3DDY is describing is a Magnetic loop antenna. He also emailed me about the same setup so I started investigating Homebrew Magloop antennas on the net. I found a site that really impressed me! http://www.laud.no/la6nca/loop/ It also started me on a project to build a Magloop for my small, pull behind camper that also gets used as a portable emergency commutation station. My problem was that almost every place that it is set up (parking lot) there is no place to hang wire for dipole antennas and no on the ground radial wires for a vertical as vehicles driving in the parking lot would be driving over them and destroying them. My Magloop element is made from 20 feet of old RG-8 coax that would be only good for throwing in a trash bin due to high loss from age. It is supported with two, one-inch diameter by eight feet long fiberglass rods in an "X" configuration with bungee cord holding the element taught in a square shape. A split stator capacitor is used for tuning the loop and a motor drive is connected to the capacitor for remote control operation. Here I went a little different than most Magloop tuning setups. My capacitor is mounted at the top of the loop where the ends of the coax element are connected to it and the motor drive is at the bottom of the loop with two 3/8-inch electric fence post fiberglass rod between them so there are no wires crossing the loop. This keeps the amount of conductive parts to a minimum inside the circumference of the loop element. Only a 3/8-inch bolt is used to attach the two fiberglass rods together and also acts as a hinge so the rods may be folded for transport. Also there is a 3/8-to-3/8 copper tubing compression fitting used to connect the two 3/8 fiberglass fence rods together as they only come in 4-foot lengths. Testing the Magloop mounted to the top of the camper shows a 1 S-unit loss when compared to a 40-meter dipole at 60 feet. Testing with another 40-meter dipole at 20 feet shows a 1/2 S-unit improvement for the Magloop over the low dipole. On 20 meters the Magloop was as good as a dipole and in one instance was a 1/2 S-unit better than a low mounted dipole. As for comparison to a mobile antenna the difference is astounding! A screwdriver antenna on 40 meters requires a 500-watt amplifier to provide the same received S-unit reading on a distant station when

compared to the Magloop antenna and only 100 watts output! The best thing about this antenna is it can be assembled and put into operation in less than five minutes by one person. I am currently working on an 80-meter version. This one will cover 80,60,40, and 30 meters and will be made from four, ten feet 3/4 inch copper plumbing pipes and can be mounted to the side of the camper for transport. A second Magloop to cover 20 through 10 from a single 10 foot length of 3/4 plumbing copper pipe is also in the works to replace the fold up Magloop and will be more efficient and it will be small enough to transport laying down in the bed of the truck.

I didn't think it was a Magnetic loop. Maybe it is.???
A standard 1/4 wave vertical has distributed capacitance from the whip to ground. The higher up the 1/4 wave you go the lower the capacitance is . The current in a 1/4 wave antenna likewise diminishes as you go up.
Having a capacitor from the tip to ground helps boost the current further up the length for better radiation. If you take it to the extreme then when the tip is fully grounded as a direct short then the antenna becomes voltage fed and our usual tuners won't handle that excursion.
Scott, you were considering a Magnetic Loop on a vehicle and I suggested this as an alternative because I had good results with it.
I was looking at the tuner unit that I "liberated" all that time ago and it consists of a roller coil and a capacitor hoked up in parallel.
The heavy braid under the truck was used to short all the truck parts from front to rear to improve the grounding return. It also stopped a lot of noise.
From what little I know of Magnetic antennas (nothing) I thought they operated in a different way to conventional antennas as they are physically small and have the power coupled into them by a smaller loop. If you are right that this is a variant of a Magnetic antenna then Jim's 40M loop is the biggest Magnetic in the USA.

I did almost the same thing. In my case I was using 450 ohm ladder line straight to the tuner from the antenna and I had a RF problem (It would shut off my computer when I would transmit). So I took a short length of coax cut it in half and soldered the shields together and then soldered one side of the coax centers to the ladder line. Then hooked the other end of the coax to the tuner. Now I have no RF problem in the shack, and it still tunes 40 thru 10m
fine.....

Hello Jim and everyone:

Well the antenna experiment was a success. I now have a semi inverted V antenna made from totally RG-6 and it receives *really* good. Just at twilight now for two straight nights I have tuned into the 20/40/80 mtr bands and am receiving all sorts of DX including Ve's and JA's. Pretty nice for someone who doesn't really know what they are doing even if I do say so myself.

Now I am really fired up. With the real-estate that I have I should be able to do some sort of beam antenna. I am on just a little less than an acre of land and not too many trees just a couple in the back yard about 50 feet tall.

Now I am wondering if a loop antenna would be good on 20 mtrs or if I should target only the lower bands with it. Most of the articles I have been reading about them talk about them being on the lower bands.

Tnx fer all the help everyone,
Rev Robert L Autry

I use a 40 meter horizontal loop on 40 thru 10M. It works great on 20 and 17. I've worked antartica on 20m with it. I've also worked the UK and Germany on 17 with it.. Just this week on all three. Loops cut for a lower freq seem to work better on the higher freqs. They have a lower take off angle.

I tried the capacitor on one side of the ladder line feed to "steer" my 160-meter loop. There is no effect in trying to shift the gain lobes around with the capacitor by unbalancing the feed line. All I managed to do was change my tuner setting, a lot! The only thing that?s going to work is to switch the feed point to a different point on the loop element. This might help out on 40 meters and above with a 160-meter loop with at least 1/4-wavelength height above ground. I did try this using two relays and did notice a slight difference in received signal strength on some stations but nothing that would warrant the time and work involved. I removed it due to the weight of the relays and feed line between the feed points and the required control box to replace the jerry rigged setup to control it.

If you look at a Magnetic loop you find a single turn element with a variable capacitor used to tune the element to the desired frequency. Putting the tip of the whip to ground with that capacitor between them and then using the coax brad to ensure a good conductive path did indeed result in a Magnetic loop antenna. The rubber tires would insulate it from ground very well. The L-network would be just fine for matching the loop impedance to the transceiver. Normal Magloop antennas use a second 1/5-diameter loop of the main loop to couple the RF to it. Also a gamma type feed can be used to tap a point somewhere along the circumference will also provide a 50 ohm match and most builders use these methods to feed it as it's cheap and easy to do. I found that you can also use 450 ohm ladder line by taping two evenly separated points Delta match style along the loop element for the proper match and a 9:1 Balun to transform it to the proper 50 ohm match. This will only work on a single band. The advantage is that the capacitor need not be variable and an antenna tuner is used to provide full single band coverage with a 1:1 to 1 SWR match. Contrary to what some "experts" say about element and capacitor losses in a Magloop where the capacitor is not welded across all the vanes and stator elements and non-soldered joints between the capacitor, element and add on door knob capacitors used to extend the range of the variable capacitor if care is taken with these connections very little loss will result.

Scott, If you try it on 20 Meters where the lobes of the pattern are more and more pronounced, you will see a big difference when you change the feed point. On my suggested experiment, I mentioned to the other Jim that changing a series capacitor would effect the tuner settings. By the time you have the tuner retuned the signal strength of the other station has altered anyway and you can never get an accurate reading. That is why we suggested plotting the loop pattern or at least taking signal strength readings from set positions for comparison.

794. Any Minneapolis area hams here?

Yahoo group: SkyWires
Date: 2004-09-30 01:36:41 UTC
From: George
Topic: 794 Message: 794

Hi,

Is there a Minneapolis area ham in this group who can help me put up a wire antenna? I'm 60 and have some back and leg problems that prevent me from being agile enough to get one up high enough for DX work.

I live in the southwest suburb of Bloomington and rent; the yard has some trees but they may not be high enough to get a half-wave or more in height for 20 meter operation. I'm wondering about buying a telescoping mast to help get the center of the antenna as high as possible.

If you're in my area and can help I'd be very grateful. I'll be happy to pay for assistance.

Thanks!

George W0QU

795. Dr. Ace... Question regarding Ground / Horizontal Polorization

Yahoo group: SkyWires
Date: 2004-10-02 10:30:13 UTC
From: kd5srl
Topic: 795 Message: 795

First of all Dr. Ace,

I'm building a 160 meter full wave loop with streight RG/8U coax to the feed point, #12 solid copper insulated wire. I'm running into my shack to a LDG, AT-1000 Auto Tuner.

The lot that the skywire will be installed on is a hillside. I don't own the property on the top so I have no choice but to install the antenna on the hill side with appox. 30 degree slope in a wooded lot... about 1.5 acres to play on. :p

My question here is, if I can get it up to about 40-50 feet, (not going to be a problem) should I angle the loop to match the slope or should I have it at perfectly horizontal? Which will provide better horizontal polarization

Paul - KD5SRL

From: krmason2
Topic: 799 Message: 799

Hello all,

All I can say is WOW, it is sure fun to run a big wire antenna.

My setup would not work for most people. I live in California, and I'm on a hilside. The slope of the hill is twords the east. My antenna is not very tall, only about 27 to 30 feet off the ground and using 530 feet of wire and 450 ohm feed line. There are no trees on my property, it is a horse pasture. I slapped up some EMT pipe to my fence and the way I went.

I'm guessing that the slope is helping my antenna not be a cloud burner.

I checked out my new setup this weekend by handing out some points for the California QSO Party. I was shocked to be running 100 watts and I was the first to get through in a pileup to South Dakota on 20M. 20M seemed to be real hot as Europe and Japan was heard. Almost all the time I could hear both sides of any QSO. I could of worked all states this weekend, but yard work was needed.

The antenna tunes on 160M through 10M. I tried it on 6M but could not find the tuners seet spot.

Boy, am I going to have fun this winter....

Hi Ken,

Yes you will enjoy the Loop. I am finding my loop is stronger than anyother antenna that is on my property. its great in so many ways. yes sometimes you fish out a signal as it picks up from many directions at once. but.. the other upside is your not constantly turning a beam. I find when im in a NET the beam is more hassle than worth.

hope you enjoy your loop.. id be curious how it goes for you as time goes by. take care Bryan Kc8hps

How good is the a ground on watter pipes in your house if you have a well and plastic lines going to the well? I have heare different thoughts on this, off corse the lines are full of water which is a great conductor. All replys welcom.

Keith,

The short answer is 'not very good'. Water is a conductor of sorts but no where near copper pipe.

Hi Keith,
I agree with Dave's answer.

"The short answer is 'not very good'.
Water is a conductor of sorts but no where
near copper pipe."
Dave
VE1VQ

Pure "distilled" water is an insulator, salt water is a decent conductor.
I suspect the water in your well will be a very poor conductor.

I assume you have copper pipes connecting taps, hot water tank etc ... This complex will be the ground .... the plastic pipe (with or without water) will be nil.

Topic: 805 Message: 810

Hello again Keith,

If all of the pipe connection to the well is plastic then there is no benefit to using it as a ground, either DC or RF. If some of it is copper, the part in the house, then there may be some use as an RF ground depending on the resonance of the copper.

Connecting to the water system may lead to RF burns from touching the taps. Always a pleasant experience. Even worse if the xyl is the one gaining the experience!

I apologize if my previous remark came across as flippant.

BlankThank you Dr. Ratcliff:

Yes the ones I am referring to were sent privately and *very* much appreciated.

This is such a wonderful group as a result of this group and a little bit of study of my own based on the resources from many of the answers that I received I now have two *very* efficient antennas.

One for 40 Mtrs and one for 80 Mtrs. The worst case of which covers over 3/4 of the band, the other misses only a few kHz to being a perfect 1.5 swr on my ic-730 at 100W. The Bazooka is a *really* nice antenna and *so* quite.

We have been enjoying listening to the local stations up north on CW and RTTY and others mostly out of VE land.

Now my son believe it or not has found out in the woods where someone before we moved here left a spool of RG-6 cable. About 850 feet from what I can tell. The spool was 1000 feet originally. We are *really* excited about the prospects of this find. :0)

Now we am *seriously* looking into the type of antennas that you fellows are always going on about. they sound *really* neat and *very* efficient. At least I think I should have enough wire to do something with now. We hope we do.

At any rate, you can bet that we will be listening intently to *every* post from now on.

Thank you again,
Robert L Autry

816. Grounding My Reply

Yahoo group: SkyWires
Date: 2004-10-08 18:27:21 UTC
From: Bryan
Topic: 816 Message: 816

I have just read the posts on Grounding.

If one is forced to use water pipes I would think it prudent to use to ground clamps and a #4 solid copper wire to span the plastic pipe and make a true connection to ground at the pump/well Head.

As for myself I use a 6ft copper ground rod driven under a very moist eve of the house.. (one where rain collects often) I have put some salts in a channel around the stake to enrich the ground effect. some people like regular Salt.. I personally like magnesium Sulfate << Epsom Salts.. less corrosive and I get basically the same results.

I plan however to enhance my grounding situation next spring by going to copper
pipe burried about one foot below ground exstending from the existing ground rod in several directions.. this should allow for a better absorbtion of energy..(more surface/ soil contact) should I take a direct hit with
lightning.

The one problem with a standard ground rod, especially in a sandy soil base, is the lack of surface area for absorbtion is dissipation of
energy. often in sandy soil lightning will ground through a standard ground rod as it normally would. but since it is below ground you dont see the
effects. what in essense takes place is, the energy turns the sand/silica to GLASS due to instant INTENSE heat of the strike. thus Insulating the ground rod further from
the soil.
What has happend here is the energy could not absorb into the ground fast
enough, over heated the soil around the rod.
this can be
dangerous as far as the next lightning strike is concerned. just a thought to
keep in mind as you further plan your Grounding needs.

Because the ground (as in dirt) around here is very rocky, electricians are allowed to use the plate style of grounding in lieu of rods. I remember a radio installation job some years back that called for ground rods at every base station and repeater location. We had to drive them in at a very shallow angle.

Most all electrictions here use plates now.
I have a 10' rod straight down, and an other 10'laying flat joined to it, and down about 2' like you where it is wet.
I see as a kid a direct hit from lightning and I can tell you it dont matter what you use for a ground if that happens. I will never forget our barn with all the lightning roods and grounds it had, and the lightning just riped it apart so I for one try to unhook every thing in storms.
I think grounding in storms just helps with the static charge if the storm is close at all.
I had it dammage a tunned from a strike about 12 miles away two years ago.
Just my two cents Canadina so maybe only 1.8 cents?/

When not in use I keep the 1000' loop disconnected from all equipment and a 500 ohm resistor across the terminals where it enters the shack. I used to use a clip lead across the terminals until I saw the clip lead swing toward a nearby outlet cover (metal) just prior to thunder claps during a storm a few years back.

I install my ground rods in the following way. The ground rods are made from 10 ft lengths of copper water pipe. I couple a water hosepipe to the end and use the water jet to drill a hole in the ground. The copper pipe slides into the ground as it follows the water jet. I'm fortunate that my ground area is sandy and the copper pipe doesn't hit too many stones as it slides into the ground.
For better ground, "drill" 2 length of pipe in opposite directions into the ground so that the ends are close together for connecting them together.

HI Dave,

Yes you are very correct. I have considered plate grounding,, mainly because I dont like digging that well.. If your able to do that I would think it would /could be superior to a ground rod, especially for current load handling.

My name is Alvin Mirabal and my call is WP4IDK.

Besides enjoying ham radio and playing with a 40 Meter sky loop antenna I am also a SW listener and for this part of the radio-hobby I am an avid user of the Yaesu FRG-7700 general coverage receiver.

I have found that there was not a users group in the web to support this fine receiver and I decided then to create one.

Its location is:

http://groups.yahoo.com/group/FRG-7700/

Inside this group YOU can be find a collection of links related to the YAESU FRG-7700 receiver like repairs, modifications, parts and also photos of the many accessories available.

Also it contains messages by its members on all aspects on the use and enjoyment of the FRG-7700 and of course a medium to communicate with other FRG-7700 enthusiasts around the world.

Thank you very much.

Alvin

824. 160 meter Skywire Resonant Frequency

Yahoo group: SkyWires
Date: 2004-10-17 21:04:33 UTC
From: wmfreddycurtis
Topic: 824 Message: 824

I have a 160 meter skywire fed with 450 Ohm Ladder Line. It is horizontal and approximately 40 feet tall in most places. My problem is when connected to the Antenna Analyzer it shows the lowest SWR reading of 1.5:1 at 11.447 Mhz. Nowhere near the 1005/1.9 = 531 ft. That is the approximate length of the wire. Resonance should be at around 1.9 Mhz. It does touch a pine tree at the "half-way" point and the ladder line is fed at one "end" of the loop. It is pulled up the tower via a pulley and is approximately 3 feet from the tower. I have used The Wireman lightning arrestor but readings stay the same without it connected. Any help or ideas about this problem would be appreciated.

How long is your 450 ohm ladder line freddy?
Made big changes in mine when I cut it.

Hi Freddy,
I agree with Keith's answer.
Here's some info you might find handy.

To avoid problems matching the antenna with high impedance open wire line, keep the feedline around these lengths.

[The WORST POSSIBLE line lengths are shown in brackets]

160 meter antenna 35-60, 170-195 or 210-235 feet
[Avoid 130, 260 ft]

Good Luck and 73, Ace - www.WH2T.com

Everyone is correct, most likely you have found a high or low impedance point along the line where you have your antenna tuner or SWR analyzer attached. Simply cut a few feet or add a few feet at a time until you get a feed line length where the impedance will be reasonable at the point where it attaches to your 4:1 Balun in your antenna tuner or your external mounted Balun. I have seen feed line tuners built that work fine and are simple and cheap. Simply take some feed line, ladder line or coax, and make a loop of 2 feet where it can be placed in and out of the feed line at will with a switch. Then make the same setup with 4 feet. Double the feed line lengths with this setup until you have the final feed line length at 32 feet. One or more of these lengths of feed line added will provide a low impedance point where it will connect to your tuner. This also works with the transceivers with internal automatic antenna tuners with a limited range of 3:1 SWR or less. Adding one or more of the lengths of feed line will provide a SWR or 3:1 or less. Use caution with the selection of feed line as with any antenna and feed line system. Remember; you're not tuning the antenna! You're just finding a place on the feed line where the impedance is reasonable. On other parts of the feed line a very high impedance and corresponding high voltage can exceed the rating of the feed line and burn out that or other sections of feed line.

Thanks for all the replies! When inspecting the feedline I noticed a respectful amount of rust on the DPST Knife switch, I bypassed the switch and 1.75:1 SWR on the analyzer at 1.9 Mhz!!! By the way the feedline length is about 45 feet from tuner to antenna. Thanks again for all the help!!!

829. 160M Loop is to long ??

Yahoo group: SkyWires
Date: 2004-10-18 13:00:42 UTC
From: ve6drw
Topic: 829 Message: 829

I recently put up a horizontal "long" loop for HF work. The shape is a triangle where each leg is 175 ft long (total loop length is 525 ft) at a height of 40 ft. I feed it with about 50 ft of 450 ohm line to a 4 TO 1 BALUN then into a LDG Z100 tuner and finally RG 213 into the shack. Each corner of the loop is supported by rope about 6 ft. from a Radio Shack steel tower

The antenna works great on all bands except on 160M, where it won't match. Taking the tuner OFF LINE and measuring the SWR and impedance at the BALUN with an Autek RF1, it shows the lowest SWR (3.8 to 1) down at about 1.650 Mhz (8 to 1 at 1.900 Mhz). Thus, it appears the loop is too long.

Before I start trimming (think twice, cut once ...), any suggestions or input? Are the corners too close to the towers?

Thanks

Dave

Attachments: 2 described; binary payloads are missing from this source WARC

I would think at 8-1 a tunner would tune it. I know mine is higher then
that in some placess but it tunes ok on all bands.

When you have a mismatch between the antenna and the feed line you will never get a true reading of the antenna SWR at that point of the feed line. First of all you should not try to trim or change the length of a Loop Sky wire antenna. What you have found is a point on your feed line that that has an impedance your antenna tuner (really a feed line tuner) cant tune out. The solution is to simply find a point on the feed line where the tuner can match the impedance that the tuner can match for your transceiver. Just remember that the feed point impedance of a loop is about 100 ohms and your using 450-ohm ladder line. The actual antenna impedance will be repeated every 1/2 wavelength along that feed line for that frequency. After you trim the feed line a few feet simply check the match on 160 meters and see what you have. You will also need to check the other bands as well as the impedance will change on the other bands as well. You may also add feed line length and do the same thing. You can also make a simple line tuner from the same type of feed line your using now. Simply take some feed
line, ladder line or coax, and make a loop of 2 feet where it can be placed in and out of the feed line at will with a switch. Then make the same setup with 4 feet. Double the feed line lengths with this setup until you have the final feed line length at 32 feet. One or more of these lengths of feed line added would provide a low impedance point where it will connect to your tuner. This also works with the transceivers with internal automatic antenna tuners with a limited range of 3:1 SWR or less. Adding one or more of the lengths of feed line will provide a SWR or 3:1 or less. Use caution with the selection of feed line as with any antenna and feed line system. Remember; you're not tuning the antenna! You're just finding a place on the feed line where the impedance is reasonable. On other parts of the feed line a very high impedance and corresponding high voltage can exceed the rating of the feed line and burn out that or other sections of feed line.

Topic: 829 Message: 837

Try an unconventional feedline configuration: drive one half of the window line, and let the other half float at the tuner - this is how I get 160 to work. You could also try to drive a shorted feedline as a vertical from your tuner's random out, but this may put a lot of RF in your shack.

I am not sure how the 4:1 inline balun will affect these configurations... but try everything before you cut anything!!

838. "Stacked" Two Turn SkyWave Loop Antennas - What's the Spacing between Turns ?

Yahoo group: SkyWires
Date: 2004-10-21 00:20:37 UTC
From: R H F
Topic: 838 Message: 838

BJ,

When considering "Stacked" Two Turn (2X) SkyWave Loop Antennas:
[Try this amount of 'Spacing' between the Two Loops.]

160 Meter Band = Two Turns of 254.5 Feet with 62 Inch Spacing
- Only 63.6 Feet per Side with a 2X Total Length of 529 Feet.

80 Meter Band = Two Turns of 134 Feet with 31 Inch Spacing
- Only 33.5 Feet per Side with a 2X Total Length of 268 Feet.

40 Meter Band = Two Turns of 70 Feet with 17 Inch Spacing
- Only 17.5 Feet per Side with a 2X Total Length of 141 Feet.

FWIW: 'Rightly or Wrongly' I used the Formula for the
Spacing of the "T2FD Antenna" to come up with this amount
of spacing between the Turns since it seems to be Frequency
'dependent' with respect to the Lowest Operating Frequency.

The Formulas for Calculating T2FD Dimensions are as follows.
http://www.hard-core-dx.com/nordicdx/antenna/wire/t2design.html
#2. The spacing between radiating wires ("B") is equal
to 3000 divided by the lowest desired operating frequency
(in kHz) and then multiplied by 3.28. The answer is in feet.

Any Rebuttal ?
Or does anyone have a Formula for a 'better' "Spacing" Number ?

DAVE,

1. Trim or Lengthen the Ladder Line.
[Not the Antenna Wire Element.]

2. Look at eliminating the Ladder Line. Place the Balun
up at the Wire Antenna Element and use Coax Cable Feed-Line
all the way from the Antenna to the Shack.

From: Dr.Ace
Topic: 829 Message: 840

Hi Dave,
I see that you have had several replies to your posting.

Let me explain my position and why I asked you -
"Is the loop made of insulated wire?"
Which by the way you have not answered that question.
And also why "I would try trimming 40 ft off and test it again".

The resonant frequency is related to the electrical length of the antenna. This is usually the physical length of the wire multiplied by the ratio of the speed of wave propagation in the wire a.k.a. velocity factor. The only practical way to measure the resonant frequency of an antenna is to use a Grid DIP METER or antenna analyzer at the antenna, Not at the end of the feed line.

An antenna that is resonant at its lowest Frequency/Band is a good thing contrary to what several members of this group appears to me to think, based on their postings!

Scott Said "The actual antenna impedance will be repeated every 1/2 wavelength along that feed line for that frequency."

The only time this will occur is when the antenna impedance and the feed line impedance are equal at that frequency.

When the antenna impedance is greater than the feed line's characteristic impedance, a maximum impedance point will appear every half wavelength from the antenna, and a minimum impedance point occurs at every quarter wavelength point between. When the antenna impedance is less than the feed line's characteristic impedance, the maximum and minimum points swap places.

Sometimes a difficult-to-match situation can be helped by changing the line length. Doing so changes the impedance seen by the transceiver or antenna tuner (and hopefully gets it within a range the tuner can handle) But it does not change the SWR on the line Or the antenna's resonant frequency.

As the old saying goes "There is more than one way to skin a cat."

IF the loop made of insulated wire, I would not hesitate to trim it and test it again".

BTW , I didn't arrive at the cut off 40 ft educated guess by pulling a number out of a hat. I used an equation.

40ft is only 7.6% of 525ft . IF my calculations are correct, And IF the loop is made of insulated wire.

IF the design Freq was about 1.9 Mhz and the loop is resonant at
about 1.650 Mhz .

Then I believe the insulated wire (If insulated wire was used) must
have a velocity factor of about 92.4%

841. Re: [SkyWires] "Stacked" Two Turn SkyWave Loop Antennas - What's the Spacing between Turns ?

Yahoo group: SkyWires
Date: 2004-10-21 18:01:40 UTC
From: Scott Erwin
Topic: 838 Message: 841

Trying to use formulas for a loop as compared to a T2FD folded dipole will not work. These are different types of antennas. The T2FD uses a resistor opposite the feed point that simply absorbs the reflected RF power that would be sent back down the feed line to the transmitter. The T2FD folded dipole formulas are used to try and limit the loss when transmitting in the amateur HF bands. If you make the resistor the same value as the feed line impedance then the resistor will keep that impedance match the same on resonant frequencies the antenna is used on. Trying to use these formulas with a multi-turn loop and no resistor to suck up the reflected power plus a multi-turn loop will not radiate as well as a single turn loop as the second wire has a shielding effect on both from the induced magnetic field. Loops produce a magnet field when transmitting and receive the magnet-induced field for reception, which is why a loop antenna is somewhat immune to non-magnet signal.

From: ve6drw
Topic: 829 Message: 842

Thanks for all who replied. I am still gathering suggestions and will be working on the antenna this weekend (pending good weather - no snow).

To answer the one question posed so far:
The antenna wire is insulated: it is #13 stranded polyethylene coated copperweld wire.

I will start by altering the length of the ladder feedline as it is the easiest to accomplish. I'll remove the tuner so that it does not affect my readings and will try measurements using my Autek RF1 with and without the balun.

I'll post the results next week.

Regards

Dave

Can anyone tell me if there are any nets on HF where antennas are discussed on a consistent periodic basis?

I hve plenty of wire and room and I am looking to make a *large* loop for 15 mtrs (the bigger the loop the more gain right?) and would like to learn more by just listening to some ot's talk about their antennas in order to get some ideas.

Tnx,

Can someone tell me how to figure the length of a single turn loop tuned for 28.250 Mhz that would be at least double a standard full wave length? I am looking to get some of the gain talked abt in the discussion on harmonics of the full wave.

Would I use the formula given for a full wave 1005/f (1005/28.250) and just double the number I get or is it that simple? And would the impedance at the feed point still be around 102ohms?

Tnx,
Lee

an *.maa file, is the file extension used by the FREE antenna modeling program MMANA. It is an excellent program made even better by being freeware. It can be found easily doing a google search on MMANA

Topic: 847 Message: 849

You would want to use an odd wavelength like 3, 5, or 7 times the standard wavelength formula. Simply doubling would give an even wavelength and the loop would have self-canceling and loss of radiated power as would other even wavelengths. At 10-meters the element size is not very large. You might want to simply build a Halo antenna for 10 meters with a rotor under it, as it would have a gain lobe off the end with the gap opposite the feed point. A 40-meter sky wire loop is not very large and has gain on 10-meters. Any loop size with an odd wavelength will produce around a 100 ohm feed point impedance. A 75-ohm coax cable cut for 1/4-wavelength times the velocity factor attached to the feed point of the antenna will give you very close to a 50-ohm match. Any length of 50-ohm coax may be connected to the 75 ohm coax for the run to your transceiver.

Tnx Scott:

I read abt that in the materials but I only hve 75 ohm coax and allot of it. So I am wondering if I use the 75 ohm coax as the loop and connect 75 ohm coax to it if I will have a match like I do with my double bazooka on 80 mtrs.

Also would the same theories apply for 15 mtrs. I may do 15 mtrs instead of 10 at this point.

851. Multi-turn loops

Yahoo group: SkyWires
Date: 2004-10-23 00:04:11 UTC
From: Mel Vance
Topic: 851 Message: 851

Has anyone done any real experimenting with multi-turn loops?

I live on a city lot about 120' by 75' and am restricted as to where support poles may be placed
and hight above ground (45feet with 10 feet 'grace'...55feet total). With trees, can get away an
80 meter loop of about 40' by 75-80'.

I have looked at the 'star loop' configuration (should be able to do that with some slight changes) and have wondered about a 'star loop' and standard 'lazy quad' hybrid. Was thinking
about something like:

Start at the center to corner 1

corner 1 to corner 2

corner 2 to corner 3

corner 3 to center

center to corner 2

continue as above, 'overlapping' corners to complete to loop.

Due to visual impact, was thinking of spacing of about 1-2 foot...an attempt to keep max. hight
and keep the neighbors from complaining any worse than they are now.

Anyone who has tried a multi-turn loop with any info on best spacing to retain good multi-band
operations, let me know what you have found.

857. 160M loop too Long??

Yahoo group: SkyWires
Date: 2004-10-24 22:00:42 UTC
From: Dave White
Topic: 857 Message: 857

Some of you have been following my exploits of a loop 160M loop that would not tune correctly on 160M -- it seemed to be too long. The reflector provided many good suggestions.

I was able to do a bit of work on it this weekend. Here is what I found:

Weather prevented me from changing the antenna wire length. However, I have discovered that the loop IS too long by about 30 to 40 ft to achieve resonance at 1.9 Mhz. It appears the overall length needs to be about 490 ft. It has to do with the velocity factor of insulated wire vs. bare wire. Thanks to WH2T and VE3BFM for this information.

I was able to alter the feedline length and it amazed me what a small difference a few feet made. By lengthening the feedline by 2 ft. I was able to tune the antenna on 160M. I tried it with two tuners and the results were repeatable. This altered the tuning on the other bands, and it knocked 17M out of the tuner's range. By lengthening the feedline one extra ft (3 ft change total), I was able to get all bands to fall within the range of the tuner. For fun, I tried changing the length of the coax at the radio AND the length of the ladder line before the balun. Both gave the same results.

The antenna performs VERY well (it helps that the bands were very good this weekend). I compared it with my Cushcraft A4S beam at 5p ft. on 20, 15 and 10M, and in most cases the beam was about 1 to 2 S units better. Of course it varied depending on the distance of the contact (DX being comparatively better on the beam). Many "stateside" signals were identical between the two.

Most likely the weather will prevent changing the antenna length until next spring, so I intend to evaluate the antenna this winter "as is", and change the length next year. Some may argue that changing the antenna length will not make any performance difference and they may be right, but it is an experiment that won't cost anything, so why not ...

Regards

Dave

858. slightly OT...plastic trees to disguise poles

Yahoo group: SkyWires
Date: 2004-10-25 06:02:35 UTC
From: Mel Vance
Topic: 858 Message: 858

Anyone tried using plastic artificial christmas trees to disguise support poles and/or towers?

Have lots of fir, pine, and hemlocks around here. Thought that if the plastic would hold up to
the UV rays, might be able to appease some of those who are not hams around here.....

Hi,
I believe it can, but I am not sure.
I was able to find very limited info on the web, NO technical specifications.
It's Manufactured by Regal and has 8 ports.

Coast CATV Supply sells them.
Their Item ID is RGL-T-RMT-108 .
They have a "Contact Us" link on their page:

http://www.coastcatvsupply.com/

They also have a BBS Forum at:

http://www.coastcatvsupply.com/bbs/

I hope this info is of some help.

From: KI4BUN / AAV4TP
Topic: 863 Message: 863

MARS, ARES, RACES - 48' Portable Antenna Mast Kits

I have several NEW IN BAG, UNUSED, UNOPENED, milspec kits containing 12- 4 foot fiberglass sections, stakes, batten spreaders, and batten nuts, all in a heavy duty rubberized carry bag. These are perfect for portable emergency operating or can be used for a permenant mast.

I have an 80 mete skyloop set up using 4 kits and it works GREAT!

A more detailed description is at:

http://cgi.ebay.com/ws/eBayISAPI.dll?

874. Moving

Yahoo group: SkyWires
Date: 2004-11-08 03:27:35 UTC
From: Burr Patterson, Jr.
Topic: 874 Message: 874

Evening Group,
I'm Burr, I have been a member for a year or so and am just
getting ready to use a loop antenna.
I am retiring to the Philippines and our house is on a small lot
so I'll need to use a loop antenna, I have used a long wire in an "L"
& slooped for years.
A few questions I can think of now are, what is the minimun size
or best size?

What would be the best wire to take with me for the antenna?

How should I ground the loop? I have telephone ground blocks that
I use now!

If there is a long side should it be north or east??

TIA,

Burr

875. 160 meter loop for mobile

Yahoo group: SkyWires
Date: 2004-11-08 21:01:09 UTC
From: tukatuk4
Topic: 875 Message: 875

Hi all

I am building a loop for my pick up for 160 meters.
The plan is to put 4 8 foot 2x4's in the rail holders on the
pick up bed this will give me a cube of 5.5 ft by 5 feet now 21
feet per turn spaced at 7.25 inches and 13 turns that would be
273 feet of wire. Thats 1/2 wave at 160.. I know there is a lot of
factors that change the formulas however the old saying the more
wire in the air the better should apply. I of course would use a
tuner to match the antenna..Any comments as to if this would work or
would I be just wasting my time..

Thank's Mark K6FEJ

From: Scott Erwin
Topic: 875 Message: 876

You would be wasting your time trying to use this for transmitting. What your thinking of building is a multi turn magnetic loop. For transmitting a Magloop normally will be one turn but two or three are possible but as the turns increase self canceling develops between the turn elements. Also, as the numbers of turns are increase the element starts to act more as a large inductor and less as a radiating element. There was an article in 73 many years ago detailing a large multi turn loop using 3/4 inch copper tubing and matched tuning capacitors on each turn. The writer said he made contacts on it but did not detail the quality. He could have done the same thing with a light bulb used as a radiating element, been there and done that! Try it sometime. Just hook up a 100-watt light bulb to your antenna tuner and with good conditions you can make contacts with it!

877. Low mounted 160M Full Wave Loop

Yahoo group: SkyWires
Date: 2004-11-09 04:52:32 UTC
From: n8tz_50
Topic: 877 Message: 877

I have recently put up a 160M loop. It is about 20 ft. off the ground. It has about 530 ft. of 14 ga. stranded insulated wire. I connected it to the shack by means of 50 ft. of 450 ohm ladder line. My ATR30 will not tune the antenna in the 160M band. I hooked it up to an old Dentron Super Tuner Plus and it will tune it, but when I try to run more than 100 watts I get alot of reflected power back into the tuner. Does being that close to the ground have that much effect on the tuning of the loop? Any ideas would be appreciated. I mainly put it up for receive, but would like to have it for transmitting also.

Thanks, Steve

878. Re: [SkyWires] Low mounted 160M Full Wave Loop

From: David Shrum
Topic: 877 Message: 878

My setup is similar to yours with one exception, I used coax and only around i5 to 20 feet of it, I'm not exactly sure of the length because it was laying around and I did not measure it. I only have the radio, no amp so I don't what more power would do. On 160 I can tune it BUT it is VERY difficult to do and then if I am lucky can only get about a +- 10 kc swing before I would need to re-tune, so I seldom use 160 for that reason, also I have mine suspended against, over and around trees, another negative against me.

Steve,

Try letting one side of the feeder "float" ie disconnect one side of
the feeder at the tuner. It can either be left floating or ground it.

Peter

Hi Steve,
I had a a 160M loop.
It was about 20 ft. off the ground. It worked great.
It should be about 530 ft. of 14 ga. stranded BARE wire.
Your antenna is too long .
When you use insulated wire you need to allow for the Velocity Factor of the wire.
From the limited info you gave , I would try trimming about 5% off (about 25 Feet).

882. Re: Low mounted 160M Full Wave Loop

Yahoo group: SkyWires
Date: 2004-11-09 22:16:48 UTC
From: n8tz_50
Topic: 877 Message: 882

--Thanks everyone, I feel so stupid it hurts :-) I actually took the time today to strectch out a tape measure under the wire and found it to be 592 ft long. (have no idea how I misjudged or mismeasured that badly) I'll blame the windy weather we've been having here. HI HI I shortened it by 62 feet to get to the 530 ft length but didn't take into account the difference in velocity factor of the insulated wire. (I believe Dr. Ace is right on the money) The antenna is now resonant at 1.782 Mhz being fed with coax. Removing another 25 ft or so should put about where I want it. (1.893 Mhz) Actually the formula figures to remove 33 ft. to get it from 1.782 up to 1.893 Mhz. That will have to wait till another day as I have to start midnight shift tonight :(I will let everyone know how the final product turns out. Again thanks to everyone that replied to my problem.

883. Re: [SkyWires] Re: Low mounted 160M Full Wave Loop

Yahoo group: SkyWires
Date: 2004-11-10 00:05:58 UTC
From: Dr.Ace Ratliff
Topic: 877 Message: 883

Hi Steve,
I would try trimming about half of what the formula gives (when you get the time) .
33 / 2 = 16.5 feet .
It is easier to trim than to put back on .
It has been my experience that the formula works great with center fed dipole and/or zepp type antennas .
But when using it with loop antennas, the formula will have you trim off about twice as much as needed.
Then you end up with an antenna resonant on a higher freq than you wanted .
Then if you use the formula again, it will tell you to put back on what you just trimmed off.
I am not the only one to encounter this phenomenon .
I haven't had a chance to determine if a person needs to trim 50% or 66.6% of the amount the formula gives. My guess is 50% .
Please let me know how much you end up trimming off to move it from 1.782 to 1.893 Mhz (for my education).

I shortened it by 62 feet to get to the 530 ft length but didn't take into account the difference in velocity factor of the insulated wire. (I believe Dr. Ace is right on the money) The antenna is now resonant at 1.782 Mhz being fed with coax. Removing another 25 ft or so should put about where I want it. (1.893 Mhz) Actually the formula figures to remove 33 ft. to get it from 1.782 up to 1.893 Mhz. That will have to wait till another day as I have to start midnight shift tonight :(
I will let everyone know how the final product turns out. Again thanks to everyone that replied to my problem.

Good day; I have a similar problem in TWO newly erected antennas. (I will address the LOOP in a second posting.)

The first antenna is a 120 degree-angled inverted-vee, whose apex is at 90 feet. My inverted-vee is 126.5 feet on each leg, and made of 14 Guage THHN stranded/plastic covered wire.

It is resonant (1:1 VSWR) at 1.6, 3.0, 4.0, 10.0, 11.1, 14.1 and 15.8 Mhz. (Under 3:1 VSWR at 5.5, 7.1, 8.7, 12.6, 14.1 Mhz.)

All this is with the feedline in place. The inv-vee is fed with about 120 feet of 450 Ohm twinlead. This clear-span runs down to a 4:1 balun. From the balun, I have 40 feet of RG-8 to an LDG (model RT-11) autotuner. Eight feet of RG-8 coax to the radio completes the thing.

So, I am wondering if the feedline(s) and all of the balun/tuner stuff is causing a "good load" to be seen as I noted above?

Or, am I to assume only the LOWEST figure, here, and trim the antenna accordingly?
(Any assistance would be helpful)

> 33 / 2 = 16.5 feet .

I have two antennas that I am in need of assistance. I posted an outline for the INVERTED VEE in a previous post.

This posting has to do with a standard horizontal LOOP ANTENNA.

It is 50 feet off the ground, and made with 545 feet of THHN stranded (plastic covered) copper wire. The feedline is a run of 55 feet of 450 Ohm ladder line. The ladder line is held about five feet from the tower, etc, through the use of PVC pipe, with TEE fittings. The ladder line is fed by an Icom AH-4 autotuner. (About 12 feet of RG-8 to the radio completes the feedline.)

I see a 1:1 VSWR at .7, 2.9, 5.1, 6.1, 7.8 and 10.6 Mhz. (A dip at 1.9 Mhz yeilds 1.8:1 VSWR.) All of these figures are with the tuner BYPASSED.

I forgot to mention this in my posting on the INVERTED-VEE antenna; The LDG autotuner was bypassed in this unit also; This is how I am able to "see" a VSWR. -The tuners do struggle at times, but they both are able to "tune" on all ham bands, with both antennas.

In reading the response above, it appears that a "fudge-factor" should be applied to the STANDARD formula, when a loop is considered. With this in mind, how much should I trim? (I want to run 40 Meters SSB and also 1.9 and 3.9 Mhz with this antenna.)

Thank you! -Mike- K0JTA

Hi Mike,
I would probably just leave it like it is since it tunes all bands. But if you want to trim it , I recommend trimming 16 feet off (not taking into account the velocity factor of the wire) and try that.

I am curious, the formula that is being referred to, is this the one that is 234 divide by freq for 1/4 wave, 468 divide by freq for 1/2 wave, etc... or 1005 divide by freq, OR are we talking about another formula altogether different. I am just curious and thanks.

Hi Dave ,

The "Formula" lets you build an antenna that is really resonant at it's design freq. without the need to trim and recheck the resonant freq multiple times.
I will give you an example.
Let's use a dipole as an example.
Let's say you want a dipole antenna that is resonant at 3.750 Mhz.
You do the math 468/3.75 = 124.8 feet .
So you make a dipole that is 124.8 feet (end to end).
But, after you put it up, you check the resonant freq.
And let's say you measure that the dipole is resonant at 3.5 Mhz (Not what you wanted).

Here comes the formula!

Remember:
You want a dipole antenna that is resonant at 3.750 Mhz.
You did the math 468/3.75 = 124.8 feet .
So you made a dipole that is 124.8 feet (end to end).

Now take the TRUE resonant Freq. 3.5 Mhz and divide it by 468 .
468/3.5 = 133.7 feet

Here's the formula!
Subtract 133.7 feet - 124.8 feet = 8.9 feet
Trim a total of 8.9 feet off the antenna (4.45 feet off each end)
The antenna will now be resonant very near the original design freq.

I have used this formula many times and I know a few people who have also used it (with great success).

It has been my experience that the formula works great with center fed dipole and/or zepp type antennas .
But when using it with loop antennas, the formula will have you trim off about twice as much as needed.
Then you end up with an antenna resonant on a higher freq than you wanted .
Then if you use the formula again, it will tell you to put back on what you just trimmed off.
I am not the only one to encounter this phenomenon .
I haven't had a chance to determine if a person needs to trim 50% or 66.6% of the amount the formula gives. My guess is 50% .

Hello Ace and the group -- FWIW I do it slightly different and with so far good results. I build
my 3.750 dipole that comes up resonant at 3.5 as you say, (124.8 feet) but resonant 250 khz. lower than I want it. Then I add the 250 khz to my original freq of 3750 (or 4.0 Mhz)and
recalculate a dipole for that freq - 468/4 = 117 feet and it will be dead on my original design freq
of 3750 using all of the original components minus 7.8 feet overall length. I suppose about the same
thing only different. Hi

NØATH / Dave (Different Dave)

Hi Dave ,

The "Formula" lets you build an antenna that is really resonant at it's design freq.
without the need to trim and recheck the resonant freq multiple times.
I will give you an example.
Let's use a dipole as an example.
Let's say you want a dipole antenna that is resonant at 3.750 Mhz.
You do the math 468/3.75 = 124.8 feet .
So you make a dipole that is 124.8 feet (end to end).
But, after you put it up, you check the resonant freq.
And let's say you measure that the dipole is resonant at 3.5 Mhz (Not what you wanted).

Here comes the formula!

Remember:
You want a dipole antenna that is resonant at 3.750 Mhz.
You did the math 468/3.75 = 124.8 feet .
So you made a dipole that is 124.8 feet (end to end).

Now take the TRUE resonant Freq. 3.5 Mhz and divide it by 468 .
468/3.5 = 133.7 feet

Here's the formula!
Subtract 133.7 feet - 124.8 feet = 8.9 feet
Trim a total of 8.9 feet off the antenna (4.45 feet off each end)
The antenna will now be resonant very near the original design freq.

I have used this formula many times and I know a few people who have also used it (with great success).

It has been my experience that the formula works great with center fed dipole and/or zepp type antennas .
But when using it with loop antennas, the formula will have you trim off about twice as much as needed.

Then you end up with an antenna resonant on a higher freq than you wanted .
Then if you use the formula again, it will tell you to put back on what you just trimmed off.
I am not the only one to encounter this phenomenon .
I haven't had a chance to determine if a person needs to trim 50% or 66.6% of the amount the formula gives. My guess is 50% .

Thanks, this is probably a reason why at 160 it won't even begin to show resonant in there any where, the trees are something else I won't get into that now, that is probably the reason when I first put my loop up, in the middle of winter in a hurry, actual measurements were not tape measure to wire exact, then went back later and trimmed off about 45 feet to get it a little closer, we (my son and I) still didn't put tape to wire, figured we got it close to 530 feet long, and still won't begin to tune at 1.900, some where way below there I think, the radio won't transmit below 1.600 and besides I ain't suppose to be there any way. So later on I need to do some more trimming again. Thanks guys for your help.

Dave N8PU (the other Dave, good name too I think :))

894. Insulated Wire Correction Factor

Yahoo group: SkyWires
Date: 2004-11-11 11:58:35 UTC
From: K0PYK
Topic: 894 Message: 894

SkyWire Group...
There has been some nice discissions on getting loops to resonance. Many have been using insulated wire for there projects. I am also using 12 ga insulated wire for my wire projects. I am in the irrigation business so have plenty on hand. I have a lot of trees to go through, so I am concerned about bare wire laying in the trees.
My questions as follows:

* Is 1005/f the standard loop formula???

* I would like to use my loop for multiple bands...so is 1.775, 3.55, 7.1, 14.2, 28.4 a good design philosophy???

* When I build a 1.775 loop...the length would be...566'...What would be a correction factor for insulated wire???

* If I feed with ladder line to a balun...is there a correct length to aid in matching...such as a 1/4 wave of 72 ohm coax???

* I only have the autotuners in the rigs...so my matching extremes are limited. I built a 80 meter double extended zepp and used wh2t's 4:1 balun...works nice. I also used the dipole3 program to get the ladder line to a proper length. Is there a program like this for building loops???
Thanks...
Tom, K0PYK

895. Durability of insulated wire

Yahoo group: SkyWires
Date: 2004-11-11 13:10:22 UTC
From: charles allison
Topic: 895 Message: 895

Hi folks,

I've built up an 80 meter loop for NVIS which is working pretty good. It's made using red insulated 12awg stranded wire from the hardware store. I did have to trim it some per the 160m discussion thread and maybe should trim even more to move the resonance up. since it is only up at 15 ft. and is presently implemented with a 1:1 current balun and no ladder line it gives some strange results using the mfj269. Future enhancements are to improve the length and go with 450 ohm ladder line to one of those baluns made from romex and 1" pvc plumbing pipe, per the instructions from Dr. Ace's website?

What is the durability or expected life of the insulated wire? If all or even half of the insulation flecks off then is this going to have to be replaced or extended in length to achieve resonance again? And if this $20 / 500 ft roll of 12 AWG is going to have problems in 1 to 2 years, then would it be better to use noninsulated wire?

I'm currently planning to do a 160 m loop up about 30 feet and have been collecting pushup poles and other items for the task as there is nothing around here in the way of vegetation that grows beyond about 15-20 ft.

best regards,

Charles
wb5izd

>>""* When I build a 1.775 loop...the length would
be...566'...What would be a correction factor for
insulated wire???""<<

Hi Tom, I built an 80 meter loop last year around this time using insulated wire and found out that the antenna was about ~5% too long using the formula you mentioned. I would make it the appropriate length using the formula and then trim it for the lowest swr at the desired frequency.

I can't comment on the balun/ladder line question as I used coax.

If you build it for 160 meters you should have no trouble working the rest of the bands you mentioned..at least thats been my experience..the 80 meter loop works all the hf bands above it's design freq..I can hear good on 160 but can't tune it up with my cheap mfj tuner...wish I had the ability to put up a 160 meter loop but the woods behind my house weren't very accomodation..not to mention all the poison ivy thats everywhere..

Good luck. I'm confident you will be happy with the loop's performance..I sure am..

901. Coax loss

Yahoo group: SkyWires
Date: 2004-11-13 23:44:27 UTC
From: drizzel153
Topic: 901 Message: 901

All,

Checked my loop the other day. The swr was ok for 20m ~ 2.5 to
3.1:1 (tuneable - as expected). However, the line loss measured was
3.2 db. It should be less than that. Any thoughts on why this is?
I've checked my connections and they appear to be in order. Should
I re-string the loop? Thanks.

Was the antenna disconnected? The instructions recommend that it be
measured with the coax disconnected......

906. Length of Ladder Line

Yahoo group: SkyWires
Date: 2004-11-15 14:52:47 UTC
From: kg5i
Topic: 906 Message: 906

I'm about to raise a 80 meter full wave loop; I thought I read somewhere that I should cut the ladder line to a specific length but I cannot seem to locate that info now. I do plan on feeding the loop entirely by balanced line (450 ohm).

So does it make much difference if I used 60 feet or 100 feet; I've even heard that the more ladder line the better.....What's the real scoop??

Thanks,

Larry, KG5I

907. Re: [SkyWires] Length of Ladder Line

Yahoo group: SkyWires
Date: 2004-11-15 18:19:31 UTC
From: Scott Erwin
Topic: 906 Message: 907

You will need to check the impedance at the end of the ladder line where it would connect to the antenna tuner and trim or lengthen as required. As the loop will be used on many bands the antenna to ladder line match will be incorrect for all but a very few frequency's. This will set up a condition on the feed line where the voltage and current will be high and low on different parts of the feed line according to the frequency used. This is true for any type of antenna. The solution is to simply add a little more feed line in order to change the impedance to something the tuner can handle at the feed line end where the tuner is connected. You will need a noise bridge or SWR analyzer to properly do this. If you do not have one of these instruments you can use a SWR meter between the output of the antenna tuner and the feed line. Just cut or add feed line length until you have an SWR reading below 3 to 1. Even the internal automatic antenna tuner in a transceiver can safely handle this impedance. If the impedance is below 10 ohms and you try to use any antenna tuner to match this most likely the several thousands of volts present will cause damage the antenna tuner capacitors and/or inductor from arcing or heating. Simply add or cut a few feet of the feed line to move this very low impedance point to a different point on the line. Using a 4:1 Balun with already too low impedance is a recipe for disaster. Those 10 ohms are now 2.5 ohms on the antenna capacitor and inductor. Even full legal limit antenna tuners at 100 watts will most likely arc and burn up. Just remember that when you check the impedance so if you use the internal 4:1 Balun in the tuner you will need to open the cover on the tuner and connect your Noise Bridge or SWR analyzer to the 4:1 Balun or connect a SWR meter between the 4:1 Balun and the T network.
You can build a simple feed line matcher with ladder line or coax. Simply make lengths of feed line 2, 4, 8, 16, and 32 feet long. Add one of the lengths as required to provide impedance that your antenna tuner can handle. This can be as simple as these lengths hanging on the wall and inserted as required to fancy relays and computer control. A loop Skywire antenna is not too hard on the feed line with wide voltage swings and the feed line matcher most likely will not be

required once the feed line length is found that will
provide an impedance that will be fine on all bands
but a G5RV used as a muli-band antenna will produce
wild swings of voltage on the feed line and has
"killed" more antenna tuners than can be imagined.

Larry,
Keep the feedline around these lengths.
[The WORST POSSIBLE line lengths are shown in brackets]

80 meter antenna 34-40, 90-102 or 160-172 feet
[Avoid 66, 135, 190 ft]

Some slight trimming or adding of feedline may be necessary to accommodate the higher frequency bands.

910. Re: [SkyWires] Insulated Wire Correction Factor

Yahoo group: SkyWires
Date: 2004-11-16 00:07:06 UTC
From: Dr.Ace Ratliff
Topic: 894 Message: 910

Hi Tom,
Below are my opinions.
----- Original Message -----
From: K0PYK
To: SkyWires@yahoogroups.com
Sent: Thursday, November 11, 2004 6:58 AM
Subject: [SkyWires] Insulated Wire Correction Factor

SkyWire Group...
There has been some nice discissions on getting loops
to resonance. Many have been using insulated wire for
there projects. I am also using 12 ga insulated wire
for my wire projects. I am in the irrigation business
so have plenty on hand. I have a lot of trees to go
through, so I am concerned about bare wire laying in
the trees.
My questions as follows:

* Is 1005/f the standard loop formula???

YES

* I would like to use my loop for multiple bands...so
is 1.775, 3.55, 7.1, 14.2, 28.4 a good design
philosophy???

I WOULD DESIGN THE ANTENNA FOR 1.8 MHZ

* When I build a 1.775 loop...the length would
be...566'...What would be a correction factor for
insulated wire???

If instead of bare wire, insulated wire is used a 3 to 5% shortening may be required to obtain resonance, due too insulated wire's lower velocity factor.

* If I feed with ladder line to a balun...is there a
correct length to aid in matching...such as a 1/4 wave
of 72 ohm coax???

YES AND NO

Keep the ladder line around these lengths.
[The WORST POSSIBLE line lengths are shown in brackets]

160 meter antenna 35-60, 170-195 or 210-235 feet
[Avoid 130, 260 ft]

Some slight trimming or adding of the ladder line may be necessary to accommodate the higher frequency bands.

FROM THE BALUN USE ANY NEEDED LENGTH OF 50 OHM COAX TO REACH THE STATION.

* I only have the autotuners in the rigs...so my
matching extremes are limited. I built a 80 meter
double extended zepp and used wh2t's 4:1 balun...works
nice. I also used the dipole3 program to get the
ladder line to a proper length. Is there a program
like this for building loops???

RJELOOP1 AND RJELOOP2 AND MANY OTHER PROGRAMS CAN BE DOWNLOADED FROM :
http://webpages.charter.net/crstrode/calcs/RFcalcs.htm

I HOPE THIS INFO IS HELPFUL.

Date: 2004-11-18 15:58:23 UTC
From: KI4BUN / AAV4TP
Topic: 918 Message: 918

Shouls anyone in this group be interested, I have a number of BRAND NEW, UNUSED, Military Surplus Camo Suport Systems. They make GREAT Antenna Masts for both portable operation or as I have done to support a SkyWire Loop.

These units are still sealed in the 40mil plastic bags from the factory and contain:

12 - 4 foot fiberglass mast sections
16 - battens (easy to mod for guy plates)
16 - aluminum stakes
4 - batten nuts
1 - heavy duty rubberized carry bag.

These make great go-kits for ARES, MARS, EMCOM. If you need one, two, three, or all four masts for a SkyWire Loop, these are just the ticket.

I am asking $25.00 plus shipping per unit. They can also be picked up in the Evansville IN area.

For more info please e-mail me at: pcsutton@... or call 270.826.9988

Best regards,

C.L. Sutton KI4BUN/AAV4TP

Hi Jay, if you are just running the antenna right into the swr meter, 1.7 is about the lowest you will see..same thing with my 80 meter loop..

Not sure why the swr changed radically, are you using bare or insulated wire?

Jay"

Im sure there are people out here more knowledgable than me but I'll take a stab at what happened. The height above ground changes the way an antenna acts which may effect the swr. But it's strange that it was acceptable when it was laying on the fence but shot up when it was raised. Or, the antenna may have been interacting with the fence and moving it away from the fence changed the electrical properties of the antenna, especially with bare wire.

Another consideration is the connections may have been compromised when you moved the antenna...I'd recheck all the connections and make sure they are true. Can you tune it down with a transmatch??

927. Re: [SkyWires] Re: what is the restance for a 40 meter loop

Yahoo group: SkyWires
Date: 2004-12-01 16:08:16 UTC
From: Scott Erwin
Topic: 923 Message: 927

The feed point impedance (Z) on any loop antenna is around 100 ohms and is variable with conditions present around the antenna such as a metal fence wire and ground coupling according to the height above ground. A SWR of 1.7 to 1 would be about right if measured at the feed point of the antenna. Do not confuse AC Impedance with DC resistance! You can't simply use a volt/ohm meter to read the impedance of an antenna. With a loop you are simply reading the resistance of the length of wire used as the antenna element. The feed line and length of it can produce different SWR readings at the transceiver end of the feed line. The reason for this is that the feed line impedance is different than the antenna impedance where no matching device is used between the antenna and the feed line. This causes changes of impedance along the feed line. To correct the problem if you plan on using the loop on 40 meters only then simply insert a section of 75 ohm coax 1/4-wavelength times the velocity factor of the coax used. Using Radio Shack RG-59 coax for 40 meters this would be 32 feet long. If you plan on using the loop on higher bands the feed point impedance will again be different but on HF bands and a loop antenna this is really no problem as long as you do not try to load the feed line and antenna on bands lower than the band the antenna was made for. The trick is to simply find a point on the feed line where the impedance will be something your antenna tuner can handle. You can build a simple feed line tuner by making different lengths of coax of 2, 4, 8, 16, and 32-foot lengths and adding then to the end of the coax feed line. This can be as simple as just having them ready with the proper coax connectors to install them as required to a fancy relays with computer control via the parallel port on a computer to switch in the required length. Using the lengths shown you can obtain a SWR 3 to 1 or lower than even an automatic antenna tuner in a modern transceiver can tune without problems.

929. 160 Dipole Help Needed

Yahoo group: SkyWires
Date: 2004-12-06 03:56:05 UTC
From: Mike
Topic: 929 Message: 929

I am new to the group so maybe this has already been covered. In the fall of 2003 I put up a 270' dipole into the trees. The center is about 40' up in a tree. (Best I can do) One end is up about the same hight but the other end is only about 25' up. (It was higher but came down this spring and I had no way to get it back up again.)

I feed it with about 100' of 450 ohm ladder line directly into my shack and into my TenTec 238B tuner. I am able to tune 75 meters and 40 meters without difficulty and can use my AL811 amp without difficulty. However I cannot tune 160. I recently got a MFJ 259B antenna analyzer to check out the system.

Here is what I got.

Freq R X SWR
1880 mhz 104 333 17.8:1
2159 mhz 51 5 1.1:1

So my antenna is resonant up in the 2.0 mhz area. So any ideas on how to get it down to 1.9 mhz. I could get the ends down but it would be tough. Can I somehow adjust the feedline to move the freq down?

Any ideas would be greatly appreciated.

From: D. Scott MacKenzie
Topic: 929 Message: 930

Your antenna is too short. By strict calculations - assuming no ground interactions:

1.880: 248.9 feet
2.159: 216.8 feet

If a simple proportion is made:

270/216 = x/248 and solving for x, it appears that 310 feet would be appropriate for your height and conditions. You can try messing with the feed line, and finding a position that would fit. There are a variety of methods in antenna books that describe the method...but I would first try adding wire - about 20 feet to each side....If you are only interested in 160M, then I would try a length of 50 ohm coax, then a 1/4 wave of 75 ohm - this would make it 125 ohm, and a reasonable match for your antenna - not perfect, but it would work, and probably not need a tuner for 160M....

Others may recommend different ways, but this way usually brings me close....

Hi Mike ,
Standard 1/2 wave dipole formula assuming bare wire is 468/Freq in Mhz = length in feet.
468/1.9Mhz = 246 feet.
Yes, you can adjust the feedline length to get a better match at 1.9 Mhz , in the station.
Add or subtract one foot at a time the recheck it.

Topic: 929 Message: 933

Success.

Since getting the ends of my "monster dipole out of the trees would be a monumental job for one guy I took the "adjust the feedline" approach. First I added 4' of 450 ohm twin lead to the existing wire and checked it on my MFJ 259B. The resonate freq was comming down, but still in the low 2.0 mhz range. Next I added about 8' and retested. The resonate freq was now in the 1.980 range. 75 meters was in the 3.8 range and 40 meters was about 6.9 mhz. I figured my Ten Tec 238B could match this so I hooked up the antenna to the tuner and sure enough I can tune 160, 75 and 40 meters with full output power.

Thanks to those who provided input. I realize getting an antenna that is closer to resonance is better but I think this will get me through the winter or until the wind knocks this antenna down.

I would do a google for the "dipole3" program. It
worked for me when I had trouble matching my 80 meter
double extended zepp. Just plug your numbers in and
find out what direction you should go.

Hi,
Every time I download and try to run DIPOLE3 , I get :

"The system file is not suitable for running MS-DOS and Microsoft Windows applications.
Choose 'Close' to terminate the application."

I am using NTFS . Any HELP ???

DIPOLE3 is one of many useful and educational
little antenna and transmission freeware programs
by Reg Edwards, G4FGQ, available at

<http://www.btinternet.com/~g4fgq.regp/>

Save time by going ahead and downloading them all
into a new "G4FGQ" directory.
Sort them out later by saving the description/download page.

<http://www.btinternet.com/~g4fgq.regp/page3.html#S301%22>

Have fun.

Since a few weeks I get the same message when I try to strart my Windoes 95 Autosketch CAD program (and other older .exe programs) on my desktop. Before that moment I had no problem. After compairing system files of my XP desk top with my XP laptop, where Autosketch still runs normally, I found an AUTOEXEC.NT file in the c:/windows/system32 directory that is on my laptop but not on my desktop. When I copy this file to the desktop Autosketch starts normally again. But after closing down the desktop and starting up again this file has disappeared. I installed the 2005 version of Norton Internet security recently, might that be the cause of this all? I did not install it on my laptop yet.

Any remarks from anybody?

greetings,

Cor Beijersbergen van Henegouwen

DIPOLE3 and the other DOS programs _should_ work
on Windows XP. I haven't installed my WXP on this PC yet
but I have used DOS programs on other WXP machines.

For Windows XP,
use Start and Run to run "cmd.exe"
to open a DOS emulation window with a "C:\" prompt.

For older Windows,
use "command.com" instead of "cmd.exe."

If you use DOS frequently, create a shortcut to
"cmd.exe" or "command.com."

Ace says,
"The system file is not suitable...I am using NTFS,..."

Not sure what NFTS is.
If "cmd.exe" doesn't work, maybe someone else
who _really_ understands these things will speak up.

Let us know how you do.

Everyone is making older DOS programs run under XP too difficult.
Simply burn a bootable DC-R with DOS and run a batch file that turns some of your memory into a virtual drive and load the program into it. You should have more than enough to take care of it if your running any flavor of Windows! Get your old DOS book out and get started making up your CD and batch file. This eliminates problems from Windows and turns your computer into something very stable and super fast!
Doing this will make DIPOLE3 very easy to run. I run Terman93 (AN-93) software with an old terminal unit and do RTTY, Amtor, and Pactor I modes with that program with true ARQ capability. With a switch of serial port wire changes via a switch I can run WF1B RTTY contest software with outstanding results, no TNC required! Something no Windows OS can do. Google terman93.zip to find this free software and also "WF1B RTTY contest software" which is also free now.

I don't have any problems running any of them (DOS programs) with XP
Pro. They start their own 'DOS' window on my computer.

Dave N8PU

My next project, someday, it to see if I can get them to run under Linux.

Ace...

Don't give up... make a DOS 6.22 bootable diskette and place Dipole3 on the same diskette... Boot your machine from the diskette and then run Dipole3 from the diskette. This will bypass the hard drive operating system and allow DOS-based programs to function.

Greetings,

Just an attempt to help. First off, NTFS is "New
Technology File System" and FAT is "File Allocation Table".

In order to have partitions larger than 2 gig, one needs to convert
to NTFS.

I am attaching 2 links for your edification. Hope they help.

Jerry, The DCTL stands for Distributed Capacitance Tuned Loop
You can find complete construction data on it in Google.
I made one with twin lead for 40 meters. It is a 4 ft square and performed well by my estimates. I made SSB 5 watt contacts out to 600 to 700 Km (400-500 miles)
The twin lead version would be great for packing as it only has to be mounted high enough to clear the ground.
I'm considering making one out of copper pipe for home or maybe mobile use. The use of copper pipe would increase efficiency and durability.

Jim...

Making a DCTL out of copper pipe would be quite expensive and very heavy... How about considering aluminum tubing, which is much lighter and far less expensive. The joints don't need to be soldered... simply held together with screw-type hose clamps...

gud luk, de Larry - W1GOR

be mounted high enough to clear the ground.
I'm considering making one out of copper pipe for home or maybe
mobile use. The use of copper pipe would increase efficiency and
durability.

Hi Larry, My reason for making the DCTL out of copper pipe is that as it is a Magnetic loop there are very high currents flowing on the skin surface and as such I chose copper tube as I'm able to solder the connections. I'm already 1/2 done and will have it working in a couple of days. I only intend to elevate the thing a few feet as long as it is in the clear. Further more copper tube and fittings were readily available from the local hardware store.
Maybe the next version will be Aluminum but I'm also considering using strips of printed circuit board maybe about 2 inches in width and bending the pair in a side by side loop or even concentric or over lapping circles spaced appropiately to retain the correct distributed capacitance value. Keeping the capacitance at about 5 to 6 pf per foot would be nigh impossible with side by side loops.
The PCB version would be very light and could be mounted on a higher pole. Any of these 2 loop contraptions will suffer from rain or snow unles sealed up but "Ideas breed Ideas". How about braid pulled on to a poly tube?
Ideally the configuration should be a circle as the radiation off the face edge of a continually bending surface is better than one that flows in a straight line. I don't know if I'm saying that correctly.
I've still got to come up with a suitable --easy to tune cpacitor to replace the capacitance stub .
Any thoughts you have or possible ideas are highly appreciated.

You could use the outer braid of the coax to make the two turn loop
but not use the inner conductor as it is shielded by the braid. The
idea is to have a loop where the proximity of the two conductors (as
in twinlead) acts as a capacitance distributed along it's length.
As such, the correct spacing would have to be maintained otherwise
it's capacitance will vary.
The two turns in the loop make a much greater inductance (X4 I think)
and the capacitance doesn't have to be that large.
On the lower bands such as 40 meters, the loop size is approximately
48" square(1219m) On a single turn loop the capacitor is placed
opposite the feedpoint whereas with this two turn loop the capacitor
is now placed adjacent to the feed point close by, but on the other
turn. I think that the voltage acrss the capacitor is not as high as
with a single turn loop but I'm not sure.
I posted some pictures of my loop but they were re-produced very
small and I'll try again for your convenience.
My loop works very well and I'm amazed at how well I'm getting out
on 40 Meters considering I operate QRP ssb and the loop is indoors
on a chair.
This would be a great antenna for apartment dwellers or for those
who can't put up antennas outside.

Happy New Year Jim and all,

I suppose the changes I made to my 1000 foot loop in November to reduce the size to 500+ feet will count as I didn't get a chance during December to do any testing.

I call into an 80m east coast net every Saturday morning and had been receiving poor signal reports for some time. Several hours of physically measuring the old loop and on the computer with EZNEC showed a slight null in the required direction. Further time showed a gain with the smaller loop (toward the south and southwest) resulting in a total theoretical gain of just under 10db.

An unused water hose reel was used to collect and store the #14 stranded/cover copper wire.

The trusty slingshot was used with a new spinning reel from Walmart (on sale for $8.90 last fall!) to get the ropes over the closer-in trees.

Several bungee cords were replaced because of fraying or over stretching. I know it's better to wait until mid winter when they fail but I figure the kidney stone attacks I was suffering at the time more than counted!

This morning was the first time on the air and signal reports (with only a few on the net) were favorable.

Hello Jim
I too was having some rf trouble feeding my 360 ft loop 160-10mtrs..
I made a 1:1 chock balun. Parts used the smaller 75 ohm coax 30 turns around a 4 inch pvc pipe.And two PL-259s..I hooked the balun from TX and then to Input of Tuner..Not only did the
RF stop but the whole system has less noisy and tunes alot easyer & faster..You might give it a try..

974. Skywire possibly overloading portable shortwave receiver?

Yahoo group: SkyWires
Date: 2005-01-02 21:27:10 UTC
From: denisnh
Topic: 974 Message: 974

Hi All. I'm a shortwave DX'er but am studying for my amateur radio license as time allows.

Currently, the radio I run the most is a Radio Shack DX-398 (made by Sanjean I believe) portable shortwave receiver. It's REALLY portable, so much so that I find it a bit clumsy to use. For antenna, I the use a Sony active loop antenna that folds up for storage and works pretty decent. I've used inverted V, random wire, dipole, etc over the years but wire antennas have a very limited life.

I'm currently setting up a skywire loop about 500' long 60' off the ground. It will be fed with RG-58 coax with the center wire to one end of the loop and the shield to the other end. The shield will be grounded to an 8' ground rod. The coax leading to the radio will be about 50' long. (Does this sound right so far?)

I have the ARRL Antenna book which describes the Skywire. For using this antenna for receive only with a portable shortwave, do I need the following:

- Loops in the coax?
- Baluns?
- Antenna tuner and what brand and model if needed?
- In place of the coax, could I get away with simple twin lead wire or lamp cord? It would be nice if I could slip this under a window.

Is there anything else I should do to prevent overloading of my radio?

Thanks,
Denis

Denis,

My recommendations - worth what you pay for them ;-) are as follows:

1. Use quality 300 ohm twinlead for the whole feedline- way cheaper and much more efficient than coax, and fits under a window.

2. Trim or add to the loop a little so that it is resonant in one of the ham bands - add another 40' and you're in the middle of the 160 meter band, which is a great loop to have... they can be used for all the higher bands with a tuner. I say this since someone with your determination will get his FCC ticket in short order. But - this is non critical for receiving, and for transmitting you can usually pull it in with an antenna tuner.

3. There's no worries about overloading a decent receiver with any antenna, provided you're not living next to Radio Havana's antenna farm or something ;-) You could rig up an attenuator if it's a problem - but I suspect not.

4. And the most important thing: Ignore any advice that you want to. The great thing about skywires is that they are largely non-critical in their design. Plus they're the cheapest antennas around... plus they work like all get out. There's all sorts of methods of hanging them, and you'll likely figure out new ways to do stuff and tell us all about it here on Skywires!

So, welcome, have fun, and get that ticket!

Topic: 978 Message: 979

You will have trouble trying to use an 80-meter loop on 160-meters when trying to use it as a 1/2 wave loop. It will be very hard to make contacts and it would be very easy to arc the capacitors or overheat the inductor in your antenna tuner. You will have others tell you to open the loop at the side opposite the feed point but as the now 160-meter dipole is in a folded configuration you will have high loss due to self-cancellation. Then there is the trick of tying the feed line ends together and feeding it as a vertical but this requires and extensive ground radial system, which is difficult to obtain on 160 meters. The only usable solution is to make a tuned feeder line for the 80-meter loop. You will still be using the loop as a 1/2 wave with poor performance but you wont burn up your antenna tuner. What you do is make some wide spaced ladder line that is at least 6 inches wide between the feed line wires. The length will be calculated by making the total length of wire equal to the wire used in a 160-meter loop, which is 530 feet. An 80-meter loop uses 272 feet of wire. Your homebrew ladder line will need to be 129 feet long plus you will need to make it at least 20 feet longer and start trimming to obtain a low SWR (on the antenna tuner side of the internal Balun) at the frequency you plan on using. The 3:1 SWR bandwidth will be around 50 MHz if you're lucky. Again, performance will be low compared to a full size loop or dipole.

May I suggest the following

MFJ 956 or MFJ 1046 http://www.universal-radio.com Part No: #2964 or 3736
also a attenuator and high pass filter for SW and low pass filter for LW. I hope this helps Its just something that I may suggest to you and also myself for my next antenna project. Take care and 73 Adam E.

I'm currently setting up a skywire loop about 500' long 60' off the
ground. It will be fed with RG-58 coax with the center wire to one
end of the loop and the shield to the other end. The shield will be
grounded to an 8' ground rod. The coax leading to the radio will be
about 50' long. (Does this sound right so far?)

I have the ARRL Antenna book which describes the Skywire. For using
this antenna for receive only with a portable shortwave, do I need
the following:

- Loops in the coax?
- Baluns?
- Antenna tuner and what brand and model if needed?
- In place of the coax, could I get away with simple twin lead wire
or lamp cord? It would be nice if I could slip this under a window.

Is there anything else I should do to prevent overloading of my radio?

Hi Folks,

Has anyone tried the Omniloop (http://www.hfantennas.com/Products.htm) setup? I just finished an 80M Loop myself and it works great but the ladder line (I believe) is giving me some RFI. I've got 100' of ladder line feeding into an LDG 4:1 Balun, then 20' of RG-8X going to the LDG AT-11MP tuner (the tuner doesn't have a wire input). Just wondered if the Omniloop's "Loop Balun" and coax works well on that Omniloop... any experience out there?

Many thanks for the helpful advice! I guess a receive antenna is not as difficult as a transmitting one would be. It all sounds very straight forward. I have had my eye on that MFJ tuner, though, and I'll probably pick one up. It can't hurt the setup and I'll hopefully learn something from it.

We've had a few moderate snow storms here in New Hampshire the last few days. I don't care for tromping through the snow and brush trying to run a wire this long. I'm now thinking I should work up to the skywire by first going with a loop and an inverted L after I get the loop working properly. The skywire can go up in the spring.

By the way, what sort of reactions do you get from your neighbors when running that much wire? I had thought about telling them what I'm doing before I start. My wife says it will just give them an excuse to complain about everything from the "eye sore" to even the slightest interference they might experience through their phones or TV.

I don't know what it is about me and rotten weather, and I suspect many of
you are the same: we ONLY work on antennas outside when the weather is rotten.
I don't know what this actually says about us, but I assume it's something
of significance.

Last winter I was on a ladder, at night, in sub-freezing weather... thinking
that
I really do have a loose screw in my head...

The loop is the least-noticed antenna design I have ever put up. No one sees
it in the trees... just the feedline is visible. So, I get no ack-ack from
the neighbors. Except when they see me in the winter, on a ladder, at night!
Then they think I am nuts.

Denis,
I agree with your wife.
Don't tell the neighbors.
I use an 80 mtr loop and a 160 mtr inverted L , they both work great.
Good Luck

Dr. Ace! I knew your name sounded familiar. I've read a number of your articles posted on the internet and they're great! I've learned a lot from them.

One quick question if you don't mind, regarding static buildup in a longwire. You had mentioned in an article that an end fed antenna should have a resistor from the center conductor of the coax feedline to ground. I believe this was 100k? Assuming the high voltage of a static charge, this resistor should bleed off all static. (I hope)

Being the worrier that I am, is there any type of "backup" static discharge device to go with the bleed off resistor? I've heard mention of neon bulbs, spark gaps, zener diodes. Any comments on this?

Also heard that some CB'ers use a "static discharge block" in their systems. I wasn't able to find skematic info or a supplier for these blocks. Anyone know anything more about them?

Thanks,
Denis

PS-That comment about the crop circles really cracked me up! :-)

Hi Denis,

End fed wire antennas can develop very high static voltages on them.
This static voltage can easily be high enough to knock the front end out of sensitive receivers.
To overcome this problem, I suggest you connect a resistor from the antenna wire to ground near the back of the receiver or from the coax center to shield where the antenna wire connects to the coax.

Only use a non-inductive resistor, carbon resistors work fine.
Don't use wire wound or metal film resistors.
The resistance value is not critical.
I suggest about a 56K ohm 1/2 watt resistor for receive only or if transmitting with up to 100 watts.
If you will be transmitting with high power "QRO", I suggest using about a 1 Meg ohm 1/2 watt resistor.
This resistor should bleed off all static build up.

A spark gap requires a high voltage before it will spark across the gap.

I have a very small neon bulb with pigtail leads connected across my telephone line in an attempt to squelch lightning discharge induced voltages in the telephone line (I lost several computer modems) from nearby strikes. The neon bulb lights when the phone rings too.

Some antenna coax switches have built in static discharge devices.

There is an item called a Blitz Bug that supposedly discharges static
http://64.233.167.104/search?q=cache:Amid6tHjw1sJ:www.acksupply.com/catalog/antenna.pdf+%22blitz+bug%22&hl=en

A conventional TR Cell is a gas discharge tube, acting as an electronic switch. This is used to short the receiver input and thus protect it. The transmitted pulse causes the gap in the cell to break down, thus forming the short circuit.

Gas discharge tubes take time to turn on, and longer to turn off again. Often a keep-alive is used to prime the cell ready for action. The gas in the cell is critical to the time it takes for it to ionize and deionize, and water vapor proves to be the most stable.

Hope this info is somewhat helpful.

993. Limited space/rules loop...

Yahoo group: SkyWires
Date: 2005-01-18 02:50:00 UTC
From: n4onl
Topic: 993 Message: 993

Hello everyone!

I'm getting back into ham radio after a few years absence and have
been researching antennas.The horiz. skyloop sounds like what I want,
but as usual what I want and what I get aren't usually the same. I've
been told by the landlady that I can put up any antenna I want as long
as its in the tree next to the house. Seems like theres always a 'as
long as' in my life, but its better than a flat NO.

Limited space, wanting to be able to put out some signal on 75 &160m
to ragchew with some local (15 to 150? miles) friends that hang out on
those bands, and with a brain thats turning to jelly from reading too
darn much. I was grandfathered to general with my old tech licence and
have no experience on any bands lower in freq. than 10m novice phone.
Yep I'm a phone guy, no CW allowed in this shack, we don't get along. ;)
But I'm planning on upgrading to extra in the next few months and have
a like new IC746 raring to TX. I have to say it beats the heck out my
old TS130, FT101ZD... on features and RX! B)

After reading abt 90% of the posts in the group you have me interested
in trying a single loop, center supported off of 4 insulated poles to
the center support mast. Size wise it looks like I'll be limited to a
40m (~132' insulated wire and ~50' high) loop, fed with 450 ladder
line (~90-100') for multiband, and a manual tuner With that in mind
the Qs begin...

1) Can I expect a good tuner to let me have some kind of signal on 75m
or 160m?
Yes I realize its a serious compromise but what in life isnt? Anyway
the main person I'd like to be able to reach on 160m lives ~15 miles
away so a unshielded dummy load would probably do that at 50ish ft.
Any further would be a bonus! On 75m the gang seems to be in a 100-150
mile radius.

2) What about a Slinky loop for extending the wire length in the same
space, or will the steel (?) eat up most of my power in resistence?

3) From what I've been reading 2 turn loops seem to self cancel, but
would a 3 turn or odd # turn loopoffset this to a usable degree?
(thinking of more wire for 75-160m but higher bands may suffer?)

4) Dr.Ace likes the MFJ989C tuner, would it or another tuner be able
to tune 75-160m with a 40m loop? (IOW What tuners would be recommended?)

5) I would like to build a mid power linear this year (4-500watts),
what wire size would be recommended for that power level.

Any comments, suggestions, etc... are welcome!

From: Mel Vance
Topic: 994 Message: 994

Still looking for more wire/lower bands within my rather severely restricted lot...

1 idea I am looking at is a modified star loop....

Could the legs on the star loop be done into a 'T' shape and still work well?
It seems to me the star loop is just the loop skywire wadded up to fit a smaller area and some additional folding should not have too much of an effect.

Should work OK - not the best, but adequately for SWL use
If antenna is a Discone - (kinda looks like a cone) - it should also work ok....

If it is a discone both it and the 75ohm coax should work ok on both TX and RX across the rated bandwidth (frequency range) of the antenna. Typically ham rigs will have better recieve sensitivity and selectivity than a scanner radio, so it should perk up your ears over just using a scanner.

If your just going to recieve, hook it up and try it out, it sure won't hurt anything. I would suggest using better coax, something with a foil shield under the braid like rg-6x, for lower loss/better RX sensitivity. Better coax at higher frequencies does help. Also you might want to research mast mounted recieve preamps for more gain. but research before you buy (if you go that route) you want one with the lowest noise rating and decent gain.

Another option would be to build a dual band beam (quad) for recieving in their area. 2 elements would give some gain without narrowing down the beamwidth too bad. Their simple and cheap to make, and the soze os less critical for RX only.

Remember that an antenna system only preforms as well as its weakest link, so optimizing the rx, coax and antenna will do wonders.

Hi ,
The antenna will work on the police scanner.
Any coax will work, BUT if you want to use TV coax V/U or 82 channel coax such as RG-6 will work much better than VHF only coax such as RG-59 type used by cable companies.

Hiya...Discones are good scanner receive antennas. I use one myself. The cable ur referring to (I think) is RG-58. It's ok for receive only, but if you intend to transmit you'll need to go to the RG8.

Hello Donnie,

What does the antenna look like..? Is it a single, vertical element, or a cone-shaped antenna with a group of spoke-shaped elements at the top..? For scanning, a Discone is the best choice because it covers a very wide frequency range. You can use TV cable between the antenna and the scanner. The difference between 75 ohm TV cable (RG-59) and 50 ohm RG-58, RG-8, or RG-8X is not much of a problem with receiving (scanning). So, you don't have to spend your $$$ for 50 ohm cable.

Just mount it up high and enjoy listening to the Police, EMS, and Fire departments.

Please help here, could be expanded to National Firefighters, Police and EMS personnel Day as well.

An idea from the son of a 9/11 firefighter... so before you delete this, just remember that this is a 14 year-old boy who lost his father on September 11th. All you're asked to do is type, point and click.

He's got a really great idea. Thanks!

Hello,
I lost my Dad on September 11th; he was Chief Edward Geraghty, Battalion 9, New York City Fire Department. He lost his life with many other heroes that day, victims of the terrorists. Firefighters from all over have come to the aid and rescue of the tragedy in New York and Washington, D.C. Many firefighters lost their lives to save someone else's. The truth of the matter is, they do this every single day.

They truly are heroes. I know many people feel helpless, especially those who live far from NYC and D.C. We all want to do something to show our appreciation, our support. I think we can... In honor of the bravery, courage, and determination of American firefighters, there should be a day in our nation to celebrate and appreciate their hard-work and never-ending passion for saving lives. I think we should
honor all those other heroes who still live today. I'm starting a petition for a National Firefighters Day. Will you help make every September 11th "National Firefighters Day"? Please join me! Thank you.

From: Mel Vance
Topic: 1007 Message: 1008

Hope I am wrong about this one, but it is very much like lots of others that were running around just after 9/11. If you look at the bottom of the message, it is looking to get a return
message with 500 names. Lots of these turn out to be 'phishing' for information for mail lists.

The idea of a firefighters/police/EMT day is great. We have a little known day for firefighters
and police in WA already.

Hi Mel,
Have you considered a Multi-Band Mini Super Loop Antenna ?
It will work 10 - 80 mtrs with a tuner.
You would need about 100 feet of horizontal space to hang it across like a dipole.

Construction Info is at
http://www.bloomington.in.us/~wh2t/Super%20Loop%20Antenna.htm

Subject: [SkyWires] star loop

Still looking for more wire/lower bands within my rather severely restricted lot...

1 idea I am looking at is a modified star loop....

Could the legs on the star loop be done into a 'T' shape and still work well?
It seems to me the star loop is just the loop skywire wadded up to fit a smaller area and some additional folding should not have too much of an effect.

Hi Mike,
I don't believe you have had any takers on your questions yet, so here's my 2 cents worth. First let me say that if you go with a "40m (~132' insulated wire and ~50' high) loop, fed with 450 ladder line (~90-100') for multiband" you very well might need to change the length of the 450 ohm ladder line.

As I state on my web page http://www.bloomington.in.us/~wh2t/zepp.html
To avoid problems matching any center fed antenna with high impedance open wire lines, keep the feedline around these lengths.

[The WORST POSSIBLE line lengths are shown in brackets]

40 meter antenna 42-52, 73-83, 112-123 or 145-155 feet
[Avoid 32, 64, 96, 128 ft]

Now on to your questions.

#1 "Can I expect a good tuner to let me have some kind of signal on 75m
or 160m?"

It will be very difficult for ANY tuner to give you a good match on any band lower than the antenna's fundamental design frequency/band. You can expect to have a VERY weak signal on 75 or 160 mtr bands.

#2 "What about a Slinky loop for extending the wire length in the same
space, or will the steel (?) eat up most of my power in resistance?"

It would be worth trying, there will be some (I squared R) loss if the slinky is steel.

#3 "From what I've been reading 2 turn loops seem to self cancel, but
would a 3 turn or odd # turn loop offset this to a usable degree?
(thinking of more wire for 75-160m but higher bands may suffer?)"

I don't believe a multi turn loop is what you need. More wire is great and the higher bands will not suffer.

#4 "Dr.Ace likes the MFJ989C tuner, would it or another tuner be able
to tune 75-160m with a 40m loop? (IOW What tuners would be recommended?)"

As I stated on Question #1 - It will be very difficult for ANY tuner to give you a good match on any band lower than the antenna's fundamental design frequency/band. You already know I like the MFJ-989C "3 KW" tuner. Also, Ameritron's True Legal LimitT ATR-30 Antenna Tuner is very nice but it costs more money.

When I was shopping for an antenna tuner the Ameritron's True Legal LimitT ATR-30 wasn't yet on the market. I did consider the Nye Viking tuner, but at around $900.00 I was unimpressed that it used a fixed value "door knob" capacitor in place of a variable.

Probably the best value or "bang for the buck" is to get an old Johnson KW Matchbox, BUT keep in mind they will not work on the 160 mtr band ! If shopping for a new Antenna Tuner, be sure to check the voltage rating of the variable capacitors. The MFJ-989C uses 6 KV caps, many other brand tuners use 4 KV or 4.5 KV caps, expect these lighter duty tuners to arc at lower power levels than their heavier duty counter parts!

#5 "I would like to build a mid power linear this year (4-500watts),
what wire size would be recommended for that power level.

" 14 Gauge will more than do the job, it will handle legal limit, 16 awg will handle the power but will break easier. On my loop I am using 272" of 8 gauge solid copper wire. I called all the electric supply houses in town, found the place that was the lowest cost, went in and told the guy "I want 272 feet of 8 gauge solid bare copper wire". He had a machine that ran it off on a spool, I asked him how accurate the machine was, he said with-in a few inches. I came home put it up with no measuring and it was a great success. That was several years ago, if memory serves me that wire cost me about $15.00

On any antenna, Bandwidth is proportional to the diameter of the conductor. The larger the diameter the lower the Q . The larger the diameter of the conductor the broader the antenna's bandwidth. By using 8 gauge solid copper wire on my 272" 80 meter full wave horizontal loop antenna I am able to cover the entire phone band from 3.750 - 4 Mhz with a 2:1 vswr or less!

Also here is one of my web pages that may be of interest to you:

http://mywebpage.netscape.com/Dr69Ace/ant.htm

Note: If you try the ANTENNA link above and you get
"Sorry, we can't find that page".
Click your REFRESH Button.
You may need to click it more than once.

Let the group know how your antenna project turns out.
Good Luck with the license upgrade and 73,

Subject: [SkyWires] Limited space/rules loop...

Hello everyone!

I'm getting back into ham radio after a few years absence and have
been researching antennas.The horiz. skyloop sounds like what I want,
but as usual what I want and what I get aren't usually the same. I've
been told by the landlady that I can put up any antenna I want as long
as its in the tree next to the house. Seems like theres always a 'as
long as' in my life, but its better than a flat NO.

Limited space, wanting to be able to put out some signal on 75 &160m
to ragchew with some local (15 to 150? miles) friends that hang out on
those bands, and with a brain thats turning to jelly from reading too
darn much. I was grandfathered to general with my old tech licence and
have no experience on any bands lower in freq. than 10m novice phone.
Yep I'm a phone guy, no CW allowed in this shack, we don't get along. ;)
But I'm planning on upgrading to extra in the next few months and have
a like new IC746 raring to TX. I have to say it beats the heck out my
old TS130, FT101ZD... on features and RX! B)

After reading abt 90% of the posts in the group you have me interested
in trying a single loop, center supported off of 4 insulated poles to
the center support mast. Size wise it looks like I'll be limited to a
40m (~132' insulated wire and ~50' high) loop, fed with 450 ladder
line (~90-100') for multiband, and a manual tuner With that in mind
the Qs begin...

1) Can I expect a good tuner to let me have some kind of signal on 75m
or 160m?
Yes I realize its a serious compromise but what in life isnt? Anyway
the main person I'd like to be able to reach on 160m lives ~15 miles
away so a unshielded dummy load would probably do that at 50ish ft.
Any further would be a bonus! On 75m the gang seems to be in a 100-150
mile radius.

2) What about a Slinky loop for extending the wire length in the same
space, or will the steel (?) eat up most of my power in resistence?

3) From what I've been reading 2 turn loops seem to self cancel, but
would a 3 turn or odd # turn loopoffset this to a usable degree?
(thinking of more wire for 75-160m but higher bands may suffer?)

4) Dr.Ace likes the MFJ989C tuner, would it or another tuner be able
to tune 75-160m with a 40m loop? (IOW What tuners would be recommended?)

5) I would like to build a mid power linear this year (4-500watts),
what wire size would be recommended for that power level.

Any comments, suggestions, etc... are welcome!

1013. Re: Limited space/rules loop...

Yahoo group: SkyWires
Date: 2005-01-22 22:05:16 UTC
From: n4onl
Topic: 993 Message: 1013

--- In SkyWires@yahoogroups.com, "Dr.Ace Ratliff" <wh2t@b...> wrote:
>>Hi Mike,
I don't believe you have had any takers on your questions yet, so
here's my 2 cents worth.
First let me say that if you go with a "40m (~132' insulated wire and
~50' high) loop, fed with 450 ladder line (~90-100') for multiband"
you very well might need to change the length of the 450 ohm ladder
line...<<

Thanks, I'd read n saved that already, I was just calculating the
short run distance, I'll extend as necessary.

>>>#1 "Can I expect a good tuner to let me have some kind of signal on 75m
or 160m?"<

It will be very difficult for ANY tuner to give you a good match on
any band lower than the antenna's fundamental design frequency/band.
You can expect to have a VERY weak signal on 75 or 160 mtr bands.<<

I realize that the signal would be weak, but weak is better than none!

As for the tuners, many of the automatic tuners will match shorter
antennas to low frequencies, so I thought the manual tuners should be
capible of it. I've set up automatic tuners (SEA, SGC, Motorola) on
small towboats that would easily match a 50' or so antenna to the 2mhz
coast guard frequency (2182khz? its been a while and SSB isn't as
dominate on towboats as it once was, cell phones, watercom and sat
communications like Qualcom dominate now). Of course they have a few
hundred ton boat on water as a ground. B)

>>>#2 "What about a Slinky loop for extending the wire length in the same
space, or will the steel (?) eat up most of my power in resistance?"<

It would be worth trying, there will be some (I squared R) loss if the
slinky is steel.<<

I've read its claimed to be 80' of steel originally, but is down to
62-3' now. Which would be one reason for their use on 80meter
shortened antennas.

I'm mainly kicking around ideas at this point.

>>>#3 "From what I've been reading 2 turn loops seem to self cancel, but
would a 3 turn or odd # turn loop offset this to a usable degree?
(thinking of more wire for 75-160m but higher bands may suffer?)"<

I don't believe a multi turn loop is what you need. More wire is great
and the higher bands will not suffer.<<<

Other than hellically wound (Slinky or emulating it) or multi turns I've not come up with another way to get more wire up, considering my limitations.

Back to the auto tuners, SGC has one (or more) with a 80' wire for a loop that will tune 75-80meters, in single or multi loop configurations. It seems to me with more wire the 160m band should be realisticly tuneable. Of course its a comprimize but without compromize I wont be getting on the air at all on the 2 lower bands.

>>>#4 "Dr.Ace likes the MFJ989C tuner, would it or another tuner be able to tune 75-160m with a 40m loop? (IOW What tuners would be recommended?)" <

As I stated on Question #1 - It will be very difficult for ANY tuner to give you a good match on any band lower than the antenna's fundamental design frequency/band. You already know I like the MFJ-989C "3 KW" tuner. Also, Ameritron's True Legal Limit□ ATR-30 Antenna Tuner is very nice but it costs more money.

When I was shopping for an antenna tuner the Ameritron's True Legal Limit□ ATR-30 wasn't yet on the market. I did consider the Nye Viking tuner, but at around $900.00 I was unimpressed that it used a fixed value "door knob" capacitor in place of a variable. Probably the best value or "bang for the buck" is to get an old Johnson KW Matchbox, BUT keep in mind they will not work on the 160 mtr band ! If shopping for a new Antenna Tuner, be sure to check the voltage rating of the variable capacitors. The MFJ-989C uses 6 KV caps, many other brand tuners use 4 KV or 4.5 KV caps, expect these lighter duty tuners to arc at lower power levels than their heavier duty counter parts!<<<

I have a old MFJ-989 on the way to play with, for $120 I thought it would be good for testing. If it won't tune a limited size antenna properly then I havent wasted $300 on a new 'C' model. Like most hams I don't have unlimited funds, but I'll spend as needed when I know something will work, or dabble in the less expensive stuff then fumbling around. ;)

>>>#5 "I would like to build a mid power linear this year (4-500watts), what wire size would be recommended for that power level.<<

" 14 Gauge will more than do the job, it will handle legal limit, 16 awg will handle the power but will break easier. On my loop I am using 272" of 8 gauge solid copper wire. I called all the electric supply houses in town, found the place that was the lowest cost, went in and told the guy "I want 272 feet of 8 gauge solid bare copper wire". He had a machine that ran it off on a spool, I asked him how accurate the machine was, he said with-in a few inches. I came home put it up with no measuring and it was a great success.
That was several years ago, if memory serves me that wire cost me about $15.00<<

If I do a limited size, center supported, loop the wire will be the least of my expenses. Price some fiberglass 40m quad spreaders! ;)

>>On any antenna, Bandwidth is proportional to the diameter of the conductor. The larger the diameter the lower the Q . The larger the diameter of the conductor the broader the antenna's bandwidth. By using 8 gauge solid copper wire on my 272" 80 meter full wave horizontal loop antenna I am able to cover the entire phone band from 3.750 - 4 Mhz with a 2:1 vswr or less!<<

Yep, or you can use 2 or more smaller conductors, spaced, to fool it into acting like a larger diameter single conductor at RF frequencies for extended bandwidth.

>>>Also here is one of my web pages that may be of interest to you:

http://mywebpage.netscape.com/Dr69Ace/ant.htm
Note: If you try the ANTENNA link above and you get
"Sorry, we can't find that page".
Click your REFRESH Button.
You may need to click it more than once.<<

Thanks Ace, but if I lived on a farm I'd just put up a 530' loop n be done with it. I'm trying to meet a restriction challenge, but it is fun trying to find a better way.

>>Let the group know how your antenna project turns out.
Good Luck with the license upgrade and 73,
Ace -
Shamelessly whoring my website since 1995
www.WH2T.com<<

Thanks Dr.Ace!
I'll post when I get something figured out or tested.

1014. Height of 160 meter loop, 40 feet or 60 feet

Yahoo group: SkyWires
Date: 2005-01-23 17:42:10 UTC
From: johnisella
Topic: 1014 Message: 1014

Does anyone have experience or opinion on the height of a 160 meter loop? I am going to be installing 4 phone poles and can get them 40, 50 or 60 feet above ground, other than the higher is better approach does anyone have hard experience or theory to support higher, 60 feet, or lower, 40 foot installation?

Thanks, John K1KSC

1015. Re: [SkyWires] Height of 160 meter loop, 40 feet or 60 feet

My loop is up at about 50' but it is very long so I think it changes the
pattern a bit. Mine is 980' so the lobes are very close and it works
great on all bands.
Just my experience not real sure, I just go with what works
for me.

Anything less than 1/4 wavelength for the frequency being used is NVIS (Near Vertical Incident Skywave), sometimes called _cloud burners_ due to the very up-and-down reflections.

I doubt for 160-meters there is much pratical difference between 40 and 60 feet height. If however, you are also using this on all the other bands some of them there will be a difference, based upon where the 1/4 wavelength height is for each band.

My $0.02. Goodluck!

You nailed it when you said that higher is always better! This is a true statement with any antenna. Horizontal loops seam to work just fine close to the ground. It may be that the ground under it unlike the voltage/current-induced signal produced by a dipole type antenna does not suck up the magnetic part of the radiated signal. It does seam to concentrate it in a tighter vertical radiated signal the closer it is to ground as compared to the frequency used. Hence, the old "Sky burner" term used to describe Sky wire loop antennas. Due to modern antenna pattern software we know this is a false statement when a large loop is used on the higher HF bands. Just put up what you can and enjoy the surprising results of a Sky wire loop no matter how high or low to the ground it is!

1019. How high??

Yahoo group: SkyWires
Date: 2005-01-24 00:00:25 UTC
From: KI4BUN / AAV4TP
Topic: 1019 Message: 1019

O.K. Here is the result of several months of trial and error in finding how high to run my sky loop.

I have my loop suspended between 4 fiberglass masts which are 48 feet tall. Each pole has its own 'flagpole lanyard' system which consists of a small pulley at the top with a nylon cord looped through it which I will refer to as a lanyard.

Each lanyard has a ceramic insulator attached. Through the other hole in the insulator is run my antenna wire. I have used 18 ga. chandelier wire, 280 feet long. This configuration allows the wire to free-float through the insulators.

The lanyards are raised one at a time to the point in height I want to operate. Using this method of adjustment, I can even change the basic shape of the loop...i.e. two oposite corners high, two lower. I have even tried "aiming" the loop by adjusting two adjoining poles low and the other side high.

What has proven to work best is a horizontally flat configuration about 12 feet off the ground. This works best for dx as opposed to flat at 20, 25, 30, 40, or 48 feet.

This post is not meant to criticize others who maintain the higher the better, but to let you know what has worked best for me.

Hi Ace and Other Guys,
Why not try the DCTL loop?
See my copper 47 Inch square 40 Meter pipe version in the pictures
under VE3DDY. It works very well and I was only using QRP on 40 M and
had solid coverage out to 600 miles BW on 40 M was 26 KHz but would
extend further with a tuner. I can provide more details if required

Ron,
I just tried it and it works fine here.
Anyway here's what is on the webpage.
Ace - WH2T

Multi-Band Mini Super Loop Antenna Info

I have heard rumors that something similar to this
Multi-Band loop antenna is available commercially
as a "Super Loop" from???
But why buy when you can build an antenna.

To build this antenna you need a lot that is at least 100 feet across.
(This can be on a diagonal).
This antenna works as a Full Wave Loop on 80 Meters and also works as 2 one wave length loops fed in phase on the 40 Meter band.
Any antenna tuned for 80 Meters should also work on 20 and 10 meters as well. If an antenna works on 40 it should work on 15 as well. A tuner will probably be needed for 10, 18 and 24 MHz Band operations.

The loop is an inverted vertical triangle with the base along the top and what would be the apex hanging down. Or it could be erected horizontally if needed.

The feed point at the bottom uses a 3:1 or 4:1 balun and is then fed with any needed length of 50 ohm coax. The top center is broken with an insulator and has a 29 feet 10 inch length of 450 ohm ladder line connected across the insulator.
IMPORTANT - The 450 ohm ladder line is shorted across at the bottom end.

Here is how I calculated the loop size.
Dimensions -
One wavelength at say 7.25 MHz = 1005/7.25 = 138.62 or 138 feet 7.5 inches. If this length is doubled and used on 80 meters as a loop Then Freq(for a loop) = 1005/(2 x 138.62) = 3.625 MHz.

The 1/4 wave stub = 246 multiplied by .88 (Velocity Factor of ladder line) /7.25 = 29.86 feet or 29' 10".

The perimeter of the 80 meter loop for 3.625 MHz = 277.24 - (2 x 29' 10")[2 x 29.86 feet = the length of both sides of the wire in the ladder line] = 217.52 ft. Let's call it 217.5 feet.

If the top horizontal span is made 99.5 feet overall and the legs 59 feet each then the balun will hang about 30.5 ft below the top center insulator.
The 29' 10" ladder line can have its bottom - shorted end - tied to the top of the balun with a short length of fishing line, weed eater line, string, or cord etc.

On 40 meters the ladder line stub automatically acts as a switch and opens the connection across the insulator so the antenna works as 2 one wave length loops fed in phase.

This antenna could also be configured as a 54' 4.5" square on a horizontal plane. The 217.5 ft loop can be pulled into almost any shape but the bigger the "aperture" enclosed area the better it will work.

I have NOT tried this experimental design yet. I believe my calculations are correct and should work.

1030. Question about an awkward site.

Yahoo group: SkyWires
Date: 2005-02-08 10:44:05 UTC
From: Bob M
Topic: 1030 Message: 1030

Good evening

I've been a member for a while watching and reviewing a lot of what is going on in this group,

I'm relatively new to Ham radio and am a Novice in Australia on the Northern Queensland Coast so currently am limited to 80, 15, 10 on HF 2mtr vhf and 70cm uhf. (I also want to be able to cover the other bands as soon as I get my full call)

I have the VHF and UHF covered by building co-linear antennas.

I have had a rough dipole up that gave me limited access to Victoria, Tasmania, Sth. Australia and a rear trip across the Tasman to New Zealand.

I now have moved to a duplex block giving me access to a large tree 30-35' for the co linears

The block is like a right angle triangle with the point cut off.

The dimensions are as follows now also please allow for the house single level brick with metal roofing on the right hand boundary looking from the street.

Right hand useable boundary is 15-16 meters with a large 30' tree as front mounting point. Then to the rear right (southern) corner a Right angle to left 26.5 meter rear boundary.
Left rear corner is about 30-45 degree inwards for a usable 11.5 meters, from this point about 60 degrees right back to the front right corner at tree.... I hope this is understandable. There is a Power line coming into the property from the front left corner so I cannot bring the left front corner any more forward.

Now I am erecting 3 poles consisting of 8.5 meters 25mm ID pipe with 3.5 mtr 25mm OD wooded rods.There is a 1 mtr overlap between the pipe and wooden rods. They will be inserted 1 meter by 500mm hole into the ground in to a concreted pvc sleeved pipe. I am only allowed 11 meters in height without council approval.

Two will be at the rear corners and one at the front left point.

Now the feed point will be the rear right section.

This is where I need ALL the help and experience that you might be prepared to offer.

I can either erect a 4 sided sky wave. a tree sided sky wave. (Horizontal loop. with the dimensions and height which would be the better resonate antenna. and do I feed it with 1:1, 4:1 balun RG213 50ohm cable.

I also intend to run a half OCF dipole 13.5m + 27m with a 4:1 balun and RG213. At a height 2 meters below the loop. Now this will need to ren either N-S or E-W which I prefer as I can get a greater distance from front right corner to rear left corner over the Tree in the middle of the loop.
Thanks for taking the time to read, digest consider and offer me Ideas.
Regards
Bob M. VK4HAY

Topic: 1032 Message: 1032

Hi Tom,

I just installed a full wave 160 meter horizintal loop in a delta shape,with plans to pull the long side out to make a square.As with all horizontal wires the height is critical,mine is only 35 feet high as 1/2 wave height would be impossible.

A 40 meter loop would need to be 66 feet high for optimum performance but don't let that stop you.If you feed this antenna with balanced feed line it will perform OK on 40 but will really surprise you on the higher bands.

My loop works Ok on 160 for high angle contacts but very little low angle radiation is evident.It provides gain on 20 and above compared to a Butternut HF6V with 36 radials and ground mounted.I can work anything I can hear on 20 and above with 100 watts and it beats out the Butternut for DX on 17 and above.

Good luck and best wishes,

Bob

From: K0PYK
Topic: 1033 Message: 1033

Tom, MM3DNU

With respect to loop configuration...just put it up the best you can and with what you have. If we were in a perfect world it would make a difference. I do not know that you would be able to tell the difference. There could be a difference between vertical and horizontal orientation. I am of the feeling that when you put up wire...put up as much as you can, for the room available. I currently have a 40 meter vertical loop and and a 80 meter vertical loop. At first I was concerned about getting a delta loop up on 40, but could not get it high enough. I played with different shapes until I got the bottom a decent height off the ground. It now has 5 sides. No difference in performance on my end.

A good resource is www.cebik.com, There are a lot of articles on loops and all antennas for that matter.

http://www.cebik.com/horloop.html

Enjoy!!! Also, I like your name...

1035. Half Mile Loop?

Yahoo group: SkyWires
Date: 2005-02-20 23:04:17 UTC
From: Kurt Barnhart
Topic: 1035 Message: 1035

Here is a question you might not hear too often. We have a weekend cottage in the mountains at 4,000 ASL. We have access to about 10 acres of woods and meadows, so we don't have too many limits on loop antenna length.

I have been working on configuring a multi-band loop for 160m to 6m. I want a wire antenna (not a tower) that will disappear visually in the trees. I will use green or gray insulated #14 or #12 wire and the loop will be about 30 to 40 feet above the ground, connected to the trees via Kevlar or Dacron ropes and insulators.

Considering that I could make a loop of anywhere from 520 feet to 3,000 feet, what would be the optimum length for 160m and 75m that would also work on 20m, 17m, 15m, 10m and 6m?

I will be using about 50 feet of ladder line as a feedline and I have a pretty good Palstar tuner that should tune almost anything. I will be running 100 watts most of the time.

Any other tips or suggestions would be appreciated.

From: Bill
Topic: 1039 Message: 1039

I am in the process of purchasing 5 acres in north central Florida. The land has been used as a pine tree farm and therefore has tall thin pine trees about every 5 feet and rows about 20 feet wide. The property is 630 X 330. Since no antennas are allowed in front of the house [and no towers at all] I will be limited to about 300X300 for wire antennas. [LOL] Would a horizontal loop be the best I can do on this property for HF operation? Interested in suggestions from anyone that has experience with large properties.

Bill

From: Erik Weaver, n0ew
Topic: 1039 Message: 1040

Hi Bill,

I have a hair under 2 acres to play with, nominally on the order of 200x400 feet on a corner lot. Towers are permitted, but mine is still laying disassembled behind my house, along with the beam.

For 2-meters I have a copper j-pole mounted on the roof above my shack. Works great.

For the high frequency HF bands I have a vertical. I think it tends to act much as a vertical dipole, or a reasonably well grounded vertical, because the metal pole (RatShack gray 1.25" TV masts) is grounded to the 8-foot grounding stake a couple feet away). Seems to work very well for 10-17 meters (feed point at 25-foot height). It would undoubtedly be improved by adding radials, but that is enough of a pain to install at 25-feet height I likely never will do so. Worked a lot of DX with it a couple years ago on 10-meters and it is a very low profile antenna (A-99 (?) by Solarcon as I recall). I haven't used it much since we began the decline into the lower portion of the solar cycle.

I also have a NVIS-style dipole behind the house fed with 300-Ohm twin lead. Roughly 18-feet above ground, and about 135-foot total length. Works well for state-wide nets and the like on 40- or 80-meters.

My other antenna is a three sided loop. All corners are supported by trees. Ladder line (450-Ohm) runs outside where it almost immediately begins to split into the antenna wire. From the window it runs up and outwards to a height of about 15- to 20-feet. The base is perhaps three feet apart and the top is perhaps 10-feet apart. Then one leg runs up to the tallest point of about 50-feet. The other leg runs to a height of about 40- 45-feet, at the 2nd highest tree. In all there is on the order of 230- to 250-feet of wire as I recall.

Next time I need a spring for supporting antennas from trees (etc.) I'll go to a truck stop, or truck/trailer supply house, and purchase springs made to pull the air lines from the trailer towards the tractor. I suspect they'll provide just about the perfect amount of tension, yet provide enough "cush" to give freely in the wind. Early on, before I knew better, I was told to "make certain I got a very heavy spring" for fear of it breaking. So I got garage door springs from Sears! WAY TO HEAVY AND TOO MUCH TENSION -- These basically provide no give, and one has broken (the spring, not the antenna wire). I can attest that loop-like antennas perform poorly and are _very_ difficult to tune when one leg is laying on the ground, heheheh!

This I affectionately call my "slooper" antenna. It generally gets better signal reports on the state-wide nets than the small NVIS-style dipole out

back. Recalling those nets meet on either 40- or 80-meters, you'll find it's height is a little better than the dipole (generally between 15% and 25% of a wavelength is considered correct for NVIS antenna height, with the upper end preferred).

I can't recall if I've used my slooper on the higher bands (10-17 meters). I certainly use it between 20- and 80-meters. I've never tried it on 160-meters. Australia was my very first contact, which is always a good sign!

If I were to work on improving it -- other than the obvious of increasing the height of each corner -- I think I'd extend the ladder line and therefore the feed point to where the legs run to the two taller trees. I might also construct a shielded twin lead with 125-Ohm coax to go through the window/wall to the outdoors (ARRL Antenna Book has a description of the proper solder scheme for various impedances, which are all multiples of the coax's nominal impedance).

It was simply much easier to install as is, which is the only reason for its current configuration: Lazy Monkey was in charge! Still, it seems to work reasonably well for me.

Wire for the slooper is bare #14 stranded copper antenna wire purchased from either the Wire Man (http://www.thewireman.com) or Cable Experts (http://www.cablexperts.com). The NVIS-style dipole is made from the "Silky Wire" sold by (I believe) the Wire Man, which is _great stuff_! Very light, very difficult to see (as is the #14 copper after it tarnished), and yet very strong. I especially like the Silky for portable antennas such as the full wavelength 80-meter loop my friend and I use for field day.

All of the above antennas are mounted on or around my house. The back half of the property is not used at all right now, except to grow weeds, heheheh!

I haven't put anything up in the back acre. I am considering push-up poles at each corner (only because towers are expensive). My understanding is these may be obtained up to 50- to 60-foot height, and with a 10-foot mast on top of that, 66-Feet height is obtainable, I believe.

With such poles in place I could string up a wire loop with (high quality marine grade) pulleys at the top of each pole. This would allow me to vary the height for either NVIS operation, or increase the height to attempt a lower take-off angle and better envelope for DX.

Before actually doing this I'll have to find out the specs of the actual metal used and determine whether they require guying, or at what height they may stand free (good time to consult with an engineer). Either they stand free or I'd need to increase the distance between the poles and the property line. I'm not too comfortable with a potential falling line that crosses my property line, which may preclude this design altogether. Still thinking on this point.

As you describe your property I'd investigate if poles are a viable option. 20-feet isn't very high for 40- through 160-meters: very NVIS! On the other hand, any antenna is better than no antenna, so bottom line is put up what you can, as high as you can, with as much wire as you can. Then of course get a good quality transmatch (antenna tuner) or roll your own.

There's my $0.02 -- It'll be interesting to see what other's suggest. I tend to lurk here more than I post, but I find this to be both an active and knowledgeable group.

Good luck and have fun!
73-Erik n0ew

Topic: 1039 Message: 1041

Erik-

Thanks for taking the time to write up your antenna farm. My property has endless tall thin pine trees so the polls are there so to speak to support long wire antennas. I thought I might suspend a large loop between the rows of trees at a few points keeping the weight low at the support points. I hope these trees don't cause me problems with transmitting.

I am allowed to remove a considerable number of the trees so maybe some thinning might be in order. Like you, I prefer easy implementations and hope I can actually get a loop up for a while.

Bill

This I affectionately call my "slooper" antenna. It generally gets better signal reports on the state-wide nets than the small NVIS-style dipole out back. Recalling those nets meet on either 40- or 80-meters, you'll find it's height is a little better than the dipole (generally between 15% and 25% of a wavelength is considered correct for NVIS antenna height, with the upper end preferred).

I can't recall if I've used my slooper on the higher bands (10-17 meters). I certainly use it between 20- and 80-meters. I've never tried it on 160-meters. Australia was my very first contact, which is always a good sign!

If I were to work on improving it -- other than the obvious of increasing the height of each corner -- I think I'd extend the ladder line and therefore the feed point to where the legs run to the two taller trees. I might also construct a shielded twin lead with 125-Ohm coax to go through the window/wall to the outdoors (ARRL Antenna Book has a description of the proper solder scheme for various impedances, which are all multiples of the coax's nominal impedance).

It was simply much easier to install as is, which is the only reason for its current configuration: Lazy Monkey was in charge! Still, it seems to work reasonably well for me.

Wire for the slooper is bare #14 stranded copper antenna wire purchased from either the Wire Man (http://www.thewireman.com) or Cable Experts (http://www.cablexperts.com). The NVIS-style dipole is made from the "Silky Wire" sold by (I believe) the Wire Man, which is _great stuff_! Very light, very difficult to see (as is the #14 copper after it tarnished), and yet very strong. I especially like the Silky for portable antennas such as the full wavelength 80-meter loop my friend and I use for field day.

All of the above antennas are mounted on or around my house. The back half of the property is not used at all right now, except to grow weeds, heheheh!

I haven't put anything up in the back acre. I am considering push-up poles at each corner (only because towers are expensive). My understanding is these may be obtained up to 50- to 60-foot height, and with a 10-foot mast on top of that, 66-Feet height is obtainable, I believe.

With such poles in place I could string up a wire loop with (high quality marine grade) pulleys at the top of each pole. This would allow me to vary the height for either NVIS operation, or increase the height to attempt a lower take-off angle and better envelope for DX.

Before actually doing this I'll have to find out the specs of the actual metal used and determine whether they require guying, or at what height they may stand free (good time to consult with an engineer). Either they stand free or I'd need to increase the distance between the poles and the property line. I'm not too comfortable with a potential falling line that crosses my property line, which may preclude this design altogether. Still thinking on this point.

As you describe your property I'd investigate if poles are a viable option. 20-feet isn't very high for 40- through 160-meters: very NVIS! On the other hand, any antenna is better than no antenna, so bottom line is put up what you can, as high as you can, with as much wire as you can. Then of course get a good quality transmatch (antenna tuner) or roll your own.

There's my $0.02 -- It'll be interesting to see what other's suggest. I tend to lurk here more than I post, but I find this to be both an active and knowledgeable group.

Good luck and have fun!
73-Erik n0ew

> I am in the process of purchasing 5 acres in north central Florida. The land has been used as a pine tree farm and therefore has tall thin pine trees about every 5 feet and rows about 20 feet wide. The property is 630 X 330. Since no antennas are allowed in front of the house [and no towers at all] I will be limited to about 300X300 for wire antennas. [LOL] Would a horizontal loop be the best I can do on this property for HF operation? Interested in suggestions from

Hey Bill,

That "Silky Wire" I mentioned is very light... 1,000-feet is less than 1 lb. It has been very durable to my experience. Good combination!

Personally I wouldn't be too worried about the trees. I doubt the attenuation is measureable at HF.

1045. Re: New QTH

Yahoo group: SkyWires
Date: 2005-03-11 05:21:04 UTC
From: nc9k
Topic: 1039 Message: 1045

Hello Bill,

I've been using both a 40M and 160M loop for the past year now. They are on 40 acres. I have been tuning both on 160 thru 10M including WARC using link couplers (the homemade one down to 160M and the Johnson KW Matchbox 80 - 10M). Both antenna's are up at 35ft. and fed with 450 ohm ladderline.

I run up to 1500W PEP into both antennas where band plans permit (the 40M loop on 160 and 80M has wild feed voltages and narrow bandwidth but is within a 1/2 S unit stateside of the 160M loop on 160 and 80M). The 160M loop (500 ft long - 95% velocity factor with the plastic coated wire) consistently outperforms the 40M loop on the upper HF bands except for the rarest of conditions on 20 through 10M (angle of radiation variations).

Each loop consists of #12 plastic coated stranded housewire supported by side-by-side 36" bungie cords attached to plastic electric fence insulators for the antenna wire to slide through. (I also have a 6 ft. safety rope alongside each bungie pair in case they ever blow in a storm. So far no failures!) The 160M loop has 6 supports in an egg shape and the 40M loop has 4 supports in a square shape. The loop endpoints are secured to egg insulators and each loop is corner fed. I cut all dangerous tree branches out of the way of each loop.

On 160M last month I worked a station running 100W SSB on 1840KC in Belize with the 160M loop. Alaska, Hawaii and all other states have been good contacts as well on 160M. On 80M I recently worked stations in Japan, Italy, and Germany SSB in the DX window with the 160M loop. On 17M I had pileups of stations waiting to work me when I fed 1500W into the 160M loop.

I had considered a 320M loop but realized its greater potential would not be realized unless I could get it at least 70 ft. up. When I move later this year or next to our 160 acre property I will put a 320M loop up about 150 ft high. I will also have a 500ft. loop there at the same height.

I would put up a 160M loop as high as I could at your QTH and hang on with all the DX you will work!

I used to run 50 foot high double-extended Zepps 80M and up. The loops I am using now perform better.

Best of fun,

73's Leland NC9K

LeLand-

Thanks so much for taking the time to respond to my inquiry. Your 160m loop sounds like a winner. My plans will probably include an antenna of that sort. Details of your construction technique is also very valuable. Perhaps we will work someday.

From: nc9k
Topic: 1039 Message: 1047

Hello Bill,

My 160M loop cost $50- in materials. Branch clearing through the woods and support tree prep (more branch clearing) took 2 days and putting the antenna up by myself about 4 hours. I put it over water saturated mineral soil (septic field over iron ore). I don't know if ground conditions matter or not for a loop? Good question for someone who knows to address. I catch a net on 14.340KC at 9:30AM EST M-F. I catch daily nets on 3947KC 5PM EST and 3982.5KC evenings at 9PM EST. I float between 1835-1850KC when I get on 160M about once a week. All on the 160M loop. Hope to see you there.

1048. NOISE on a delta loop

Yahoo group: SkyWires
Date: 2005-03-12 14:41:39 UTC
From: tom
Topic: 1048 Message: 1048

I have a problem and I feel this is just the group to help with it. The problem is a very high noise level on a Delta Loop cut for 6 meters. The level is between s6 and s9 on the meter on teh 706MIIG. The antenna is 18 feet high at the bottom. I have have had similar problems with a dipole at 25 feet. When listening to 10 thru 40 meters there is little or no noise.
I live in St. louis within 1.5 miles of the local channel 2 tower, and within 5 miles of other TV and FM/AM broadcast towers.
I really enjoy running 6 meters and with this noise it is all but impossible here in town to do. when camping i can run and have no noise but at home i can talk to some of the local guys but not over 20 miles. any help or ideas are appriciated.
thanks,
Tom, KB0QIP

What kind of noise? What modes? What times of day? Have you tried different antennas?

From: nc9k
Topic: 1048 Message: 1050

Hello Tom,

I have a 706MKIIG that experiences input overload conditions.

First thing, turn off the 706MKIIG's noise blanker, automatic noise limiter and any DSP and see if that improves reception. Having them on definately causes interference in my rig in the presence of strong inband signals.

Your most likely strong signal culprit is the Channel 2 station overloading the broadband receiver input of the 706MKIIG. Try various input attenuation amounts with the radio, including external steppable inline pads. If you find a stepped attenuation level where the interference suddenly reduces you can deduce that the 706MKIIG receiver input is overloading. You might have to run a bandpass filter between the 706MKIIG and its 6M antenna to get relief. It will have to be capable of handling the full RF output of the 706MKIIG. A low pass PI network configuration antenna tuner might be all you need to reduce the TV2 signal getting into your rig. Because of the way it is built there is not much you can do internally with the rig to correct the problem.

Good luck, Leland NC9K

1051. Noise on Delta Loop

Yahoo group: SkyWires
Date: 2005-03-13 15:49:39 UTC
From: Thomas Giella KN4LF
Topic: 1051 Message: 1051

Is the delta loop mounted vertically and is it a grounded loop like a K9AYor an ungrounded closed delta loop? If the delta loop is mounted vertically then it's picking up more noise because the local noise field is vertically polarized. Also your loop receives either unidirectional or bidirectional depending on it's termination and may have a lobe aiming directly at a local noise source. The higher up in frequency that you hear the noise the closer you are to the noise source.

1052. 4,6,8 or more WL 80m horizontal loop

Yahoo group: SkyWires
Date: 2005-03-14 13:07:31 UTC
From: Bostjan Voncina
Topic: 1052 Message: 1052

Hellow!
I have a space that has 6 high (20m) light towers in a radius that i can use to put on 4 till 10 WL or more long 80m horizontal loop.
What do you suggest ? The longer the better ?

If it comes to longer wires do you think the 4mm pvc Cu wire will be ok ? or should i go and get somethink even thicker ? Here we have strong winds (sometimes to 200km/h), but i dont want to make it too heavy.

Another question...can i use the loop with the tuner in my icom 746 ?
Or i need a tuner just for that ?
I should apply a ladder line as a feedline. How long should i make it ?

I'm really sorry for the many questions, but i realy dont want to mess this up and i want to set it right the first time.
Thank you in advance
Bostjan (Ian) S57WTT

1053. Re: [SkyWires] 4,6,8 or more WL 80m horizontal loop

Yahoo group: SkyWires

From: Scott Erwin
Topic: 1052 Message: 1053

Make the lengths odd multiples of a wavelength, as even multiples will cause problems. A 3 times 160-meter loop using 1,590 feet of wire is a good choice for size. This eliminates a problem found on single wavelength loops where the 80-meter band is operating with an even wavelength causing some cancellation of the transmitted signal. I ran one of these large loops for a year and did note a slight improvement on 80-meters but could not tell any difference over the single wavelength loop I normally operate. As for wire size, using a large diameter wire will only add weight so only use the required wire needed for strength in the wind. You will need an antenna tuner with your modern transceiver and if you can easily change the feed line length you can find a place at the end of either ladder line or coax feed to provide a SWR of 3:1 or less so you can use the internal transceivers automatic antenna tuner. Here is a link to a site that details how to change feed line length to provide a low SWR at the end of the feed line. http://www.qsl.net/w5dxp/notuner.htm . With my one wavelength loop I have found that a single 4-foot length of ladder line inserted between the end of the feed line and my 4:1 Balun will provide a low SWR on the WARC bands and I have no problems with the non-WARC bands with the 4-foot length of feed line replaced with a 1-foot length of feed line.

Hi Scott,
Great advice.
Can you please clarify one sentence for me.

Subject: Re: [SkyWires] 4,6,8 or more WL 80m horizontal loop

Make the lengths odd multiples of a wavelength, as
even multiples will cause problems. A 3 times
160-meter loop using 1,590 feet of wire is a good
choice for size. This eliminates a problem found on
single wavelength loops where the 80-meter band is
operating with an even wavelength causing some
cancellation of the transmitted signal. I ran one of
these large loops for a year and did note a slight
improvement on 80-meters but could not tell any
difference over the single wavelength loop I normally
operate. As for wire size, using a large diameter wire
will only add weight so only use the required wire
needed for strength in the wind. You will need an
antenna tuner with your modern transceiver and if you
can easily change the feed line length you can find a
place at the end of either ladder line or coax feed to
provide a SWR of 3:1 or less so you can use the
internal transceivers automatic antenna tuner. Here is
a link to a site that details how to change feed line
length to provide a low SWR at the end of the feed
line. http://www.qsl.net/w5dxp/notuner.htm . With my
one wavelength loop I have found that a single 4-foot
length of ladder line inserted between the end of the
feed line and my 4:1 Balun will provide a low SWR on
the WARC bands and I have no problems with the
non-WARC bands with the 4-foot length of feed line

replaced with a 1-foot length of feed line.

From: Scott Erwin
Topic: 1052 Message: 1055

My Loop Sky wire I currently use is 520 feet of stranded, insulated 14-gage wire. At one time I had up and used a 3 times 160-meter loop Sky wire of the same wire which was 1,590 feet long at the same height of 60 feet. There was no improvement noted with the exception of 80 meters which I think was better but as I did not have the one-wavelength 520 foot long antenna up to compare it with I must include that it was my perception that the three-wavelength loop Sky wire was slightly better on 80 meters. None of the operators that I would talk with on regular schedules could tell any difference. I did make more DX contacts on 80 meters than what I would call normal the year I had the three-wavelength loop sky wire up and operating. The problem I had with the three-wavelength loop sky wire was the fact that it was hard to put up and maintain. It was constantly breaking due to the trees it was mounted in and that length of wire requires a lot of movement between trees that are all moving in different directions due to the fact there separated so far apart. I put the big loop up when all the leaves were off the trees and it was taken down and the one-wavelength loop put back up in its place the next year at about the same time. As for DX on 80 meters, I am in the process of putting a full size 1/4 wave vertical element up in a very tall tree just like last winter and I expect to have good results again this winter. The performance of the 80-meter vertical is so much better than even the three-wavelength loop sky wire. I can use the loop sky wire as the receive antenna when operating DX on 80 meters with the vertical for the low noise properties of the loop.

Hi,
After living on small city lots all of my adult life (other than during my military service) in 1994 I moved here to this rural mini farm and decided to experiment with some larger antennas since I now have the space. I am a rag chewer and very seldom attempt to work DX on the 160 or 75/80 meter bands.

I first made a 1 wavelength 160 meter loop, then a 2 wavelength 160 meter loop, and then a 3 wavelength 160 meter loop antennas. I never intend to again put up any loop antenna larger than 530 feet of wire for 160 meters. I have experimented on other frequencies with up to a 10 wavelength loop antenna. As far as I could tell, the 1 wavelength 160 meter loop worked as well as if not better than the 3 wavelength 160 meter loop antenna. And I liked the way it performed better than the 2 wavelength 160 meter loop.

Later I built a 1 wavelength 80 meter delta shaped horizontal loop coax fed antenna that uses a 75 ohm coax Q section in the feedline. It works better than any of the 1, 2, or 3 wavelength 160 meter loop antennas on the 80 meter band. But as I said before I am a rag chewer and very seldom attempt to work DX on the 160 or 75/80 meter bands.

I now use a 1 wavelength 80 meter delta shaped horizontal loop antenna and a 160 meter band 1/4 wave inverted L "vertical" wire antenna. Two loops are more than I want to maintain. If I could only have one antenna it would be a 1 wavelength 160 meter horizontal loop !

My Loop Sky wire I currently use is 520 feet of
stranded, insulated 14-gage wire. At one time I had up
and used a 3 times 160-meter loop Sky wire of the same
wire which was 1,590 feet long at the same height of
60 feet. There was no improvement noted with the
exception of 80 meters which I think was better but as
I did not have the one-wavelength 520 foot long
antenna up to compare it with I must include that it
was my perception that the three-wavelength loop Sky
wire was slightly better on 80 meters. None of the
operators that I would talk with on regular schedules
could tell any difference. I did make more DX
contacts on 80 meters than what I would call normal
the year I had the three-wavelength loop sky wire up
and operating. The problem I had with the
three-wavelength loop sky wire was the fact that it

was hard to put up and maintain. It was constantly breaking due to the trees it was mounted in and that length of wire requires a lot of movement between trees that are all moving in different directions due to the fact there separated so far apart. I put the big loop up when all the leaves were off the trees and it was taken down and the one-wavelength loop put back up in its place the next year at about the same time. As for DX on 80 meters, I am in the process of putting a full size 1/4 wave vertical element up in a very tall tree just like last winter and I expect to have good results again this winter. The performance of the 80-meter vertical is so much better than even the three-wavelength loop sky wire. I can use the loop sky wire as the receive antenna when operating DX on 80 meters with the vertical for the low noise properties of the loop.

1057. Re: 4,6,8 or more WL 80m horizontal loop

Yahoo group: SkyWires
Date: 2005-03-15 22:49:22 UTC
From: K0PYK
Topic: 1052 Message: 1057

Skywire members,
I read with interest your discussion of various wavelength loops. I am curious as to performance of a 80 meter or 160 meter loop for multiband performance. Presently I am using a 80 meter vertical loop on all bands with a 4-1 balun. It tunes fine with the internal tuner. At the cabin I have a 80 meter double extended zepp...332 feet long with a 4-1 balun and it tunes all the bands. So my observation so far with wire antennas is ..."the more wire the better". I do not know what the limitations are, with respect to...too much wire. I look forward to your comments.

Your invited to join the Butternut-antenna group. the home page link is
http://groups.yahoo.com/group/Butternut-antennas/
This group is for the Butternut antenna user who wants to learn and
Exchange their Knowledge and 'secrets' about Butternut antennas. Learn
from fellow group members, just how the Butternut antenna works with
your Transceiver. Here you will find Information and Data on figuring
out how to plan and install your Butternut antenna. Post the Photos,
Drawings and related information about your Butternut antenna Projects
here to share with others. Share you favorite Link on the web about
Butternut Antennas. Research the groups Message Archive for the
specific Butternut antenna information that is available here.

I have a two wave leingth 160m loop and I really like it,. I had a 160m diapole before but this is mutch better. I use 450 ohm ladder line to feed it , and a MFJ989C tonner some times, some times I use a link coupled tuner that I built my self. Both work good but I like the home brew because it has no ballun , but a little harder to tune on some bands. The loop is much better in my location then the diapole was.

Hi Tom,

All of the following statements reflect my own personal experience , other people's experience may vary. I use the internal tuner in my Yaesu FT-920 for up to 100 watts and a MFJ-989C Tuner when using QRO. I have used several antenna tuners including a Barker & Williamson, Homebrews and others . All of the antennas I reference here were or are used for multiband operation (6 - 160 mtr bands using antenna tuners) with the exception of a 75 meter band Double Extended Zepp Antenna that would not load up on 160 meters due to the feedline length. I know people that had 75 meter band Double Extended Zepp Antennas that would load up fine on 160 meters and worked great.
My Double Extended Zepp Antenna was 303 feet long , I trimmed it to this length to make it resonant on 20 meters without using the tuner. It was 14 AWG Teflon insulated wire. I fed it with 450 ohm ladder line from the antenna to just outside the shack then I used a homebrew 4:1 balun
http://www.bloomington.in.us/~wh2t/balun.html
and went from it into the window with a few feet of RG-8 coax to the antenna tuner.
It was a very good antenna with the exception that mine wouldn't tune up on 160 meters.

My observation has NOT been ..."the more wire the better".
I made a 160 mtr band 1/4 wavelength inverted L "vertical" antenna, then a 160 mtr band 3/8 wavelength inverted L antenna, then a 160 mtr band 1/2 wavelength inverted L antenna, then a 160 mtr band 3/4 wavelength inverted L antenna. I discovered, stick with the 1/4 wavelength inverted L antenna.

I have used a 1 wavelength 160 meter loop, then a 2 wavelength 160 meter loop, and then a 3 wavelength 160 meter loop antennas. I never intend to again put up any loop antenna larger than 530 feet of wire for 160 meters. I have experimented on other frequencies with up to a 10 wavelength loop antenna. As far as I could tell, the 1 wavelength 160 meter loop worked as well as if not better than the 3 wavelength 160 meter loop antenna. And I liked the way the 1 wavelength 160 meter loop performed better than the 2 wavelength 160 meter loop.

Later I built a 1 wavelength 80 meter delta shaped horizontal loop coax fed antenna that uses a 75 ohm coax Q section in the feedline. It works better than any of the 1, 2, or 3 wavelength 160 meter loop antennas on the 80 meter band. But as I said before I am a rag chewer and very seldom attempt to work DX on the 160 or 75/80 meter bands.
I currently use a 80 Meter Full Wave Delta shaped horizontal Loop antenna on the 6 thru 75 Meter bands with a tuner. I am very pleased with it! I also currently use a 160 Meter band 1/4 wave inverted L "vertical" wire antenna. It will tune 6 thru 160 meter bands!

Two loops are more than I want to maintain.
If I could only have one antenna it would be a 1 wavelength 160 meter horizontal loop and a good antenna tuner !

1061. Re: [SkyWires] Re: 4,6,8 or more WL 80m horizontal loop

Yahoo group: SkyWires
Date: 2005-03-16 13:22:06 UTC
From: Dave
Topic: 1052 Message: 1061

I started out with a 540' loop and when the woodlot behind the shack was cleared, I increased it to 1000'. Both were fed with the same 450 ohm twinlead at about 30-40 feet.

My on the air time is usually on an early Saturday 80M morning net with check-ins from Eastern Canada down to Washington DC.

I've noticed over the last couple of years that the larger loop just didn't seem to be as good as the smaller but put it down to band conditions or the sun spot cycle.

It wasn't until I ran the loops thru EZNEC that I found out the problem. The larger loop had a small null toward the eastern US. Modeling the smaller configuration showed a bit of a gain the desired direction (9db theoretical difference!). Not so small.

Reducing the loop to the original dimensions has given a definite increase to signal levels on both ends.

The moral of the story is, despite all the claims of 'bigger is better', you can't always know for sure unless you do the plots with one of the antenna software programs like EZNEC.

Hi Kurt,
I know you didn't ask me, But here's my observations for our other reader's benefit.
I had a 3 wavelength 160 meter loop antenna it was 1587 feet, I used a 1.9Mhz design freq. Art Bell's loop is 1595 feet and up higher than mine was. As far as I could tell, the 1 wavelength 160 meter loop worked as well as if not better than the 3 wavelength 160 meter loop antenna on 80/160 meters.

Later I built a 1 wavelength 80 meter delta shaped horizontal loop coax fed antenna, It will not load up on 160 meters.Experimenting , I first fed this antenna with all 50 ohm RG-8 coax , then I tried feeding it using all RG-11 75 ohm coax. It made NO difference.It now uses a 75 ohm coax Q section at the antenna feedpoint in the 50 ohm RG-8 coax feedline. It made a BIG difference on 80 meters! It also works quite a bit better than any of the 1, 2, or 3 wavelength 160 meter loop antennas on the 80 meter band.
But as I said several times before I am a rag chewer and very seldom attempt to work DX on the 160 or 75/80 meter bands. Although I have worked all 50 states with the 80 meter delta shaped horizontal loop coax fed antenna.

One last thing, I NEVER use a balun at a loop antennas feedpoint.

I didn't model anything larger. I did the physical measurements between available trees for smaller ones (and ran the plots for those) but settled on the 540' version in the end as that gave me the best theoretical signal level to the eastern seaboard.

I can't imagine that the few extra feet would make any difference.

One thing I didn't try was to shift the feed point on the plot to see if that made a difference to the pattern of the large loop. Easy to do on the computer but not so easy to do with the actual antenna.

Both loops made/make use of available trees and aren't the classic square shape.

On a 1-wave 80mtr rectangle loop I had up, feed point did make a difference...feed on a 'short' side resulted in a hole in coverage on 20mtr. Due to the heavy NVIS mode I had, do not think it would change anything on 80mtr on the rectangle loop.

Shape does play a role in the pattern, and as the shape gets strange, feed point will play a
role, also.

Thanks, Dave.

I have access to about five acres of woods and meadows located about 3,800 feet above sea level near San Diego.

I have been planning to tie ropes in the tallest available trees to make five outside supports for a large loop.

So, the perimeter of the wire loop will be on the inside of the circle of tall trees with the supporting trees in a circle outside the wire perimeter with ropes pulling the loop outward to form an irregular wire pentagon. I've been planning on a 1,040 or 1,050 foot loop for 3.840 MHz and 1.920 Mhz.

I will be feeding the loop with ladder line and an MFJ tuner.

Do you think this will work? I will be running only 100 watts. I will use insulated 14 gauge or 12 gauge wire from Home Depot. Will I have a problem if the insulated wire touches some leaves or small tree branches in the meadow when the wind blows?

See below. The wire is red and the ropes are black.

Thanks,

Kurt, N6MD
Emacs!

Mel,

I've been quite happy with my loops over the years. They've worked much better than the various random wires and dipoles I've had. Fed with twin lead from a home brew balanced tuner. Support rope over the trees to two foot bungee cord for wind absorption (four places) and a fifth (fixed) point on the end of a barn.

Hello Kurt,

You should have no trouble from branches and leaves with insulated wire and that power level.

I've found the price from Home Depot is about the same in the US compared to here in Canada (compensated for the $exchange) I keep a spare 500' roll of #14 stranded in case of loop breakage from the wind but it hasn't happened yet. A support line or section of bungee cord has always been the first to let go.

I used #12 for a while but found the extra weight caused problems.

For a few years, I used electric fence stuff (stranded nylon with a few stands of aluminum wire woven in. That was nice and light but I had to depend on a mechanical connection. In the last couple of years the price on that has sky rocketed. I did find some at a cheaper price but it turned out to have stainless steel instead of aluminum

You might notice a difference in tuner settings from dry to rain conditions but should be nothing major that the tuner can't handle.

On my set up, the wire does not touch any part of the tree but is supported by nylon rope thru the tree to a two foot bungee cord (with hooks). The rope is tied to one hook and the other to a pulley or nylon swivel (salt water fishing supply places all around here). The loop wire is run around the pulley or through the swivel. The lower end of the rope (next to the ground) is either tied off to a concrete block or to another tree.

With the wire not touching any part of the tree the effects of rain vs. dry is minimized.

FYI,
My 272 ft , 80 mtr loop is made of 8 gauge BARE solid copper wire "ground wire type". It touches several tree limbs and lots of leaves in the summer. I regularly run over a KW into it. I can see almost NO difference between dry, wet, or ice conditions. The MFJ-989C antenna tuner might tune just a small amount differently.

Kurt,

For pulleys you only need a two or three inch one. Anything larger will have a bigger groove giving more chance of the wire slipping out.

Lowes used to carry a small one that was good quality. I can't remember the name of the manufacturer (seems to me that it started with 'EVER...') but do remember it was located in CT. I called the plant to find out who in Canada handled them but, at the time, no one did. I don't remember seeing any in Home Depot but it was several years ago when I looked.

1073. A 4.1 balun or a 1.1??

Date: 2005-03-25 18:38:22 UTC
From: radioman1044
Topic: 1073 Message: 1073

Hello,
New to the group here so here it goes. I am running a 160 meter loop up 50 feet and now have it fed with 60 feet of 300 ohm twinlead running down into the shack to the back of the might fine junk 986 4.1 balun. It Really plays great on all the bands and tunes easy. I have heard that i really sould have a 1.1 balun on it if I want to work the upper bands. I have a nice and DX engineering 10 kw 1.1 tuner balun, that I have tried in place of the internal 4.1 on the 986 and don't seem see much of a differance on receive or transmitt.
I
have also heard that the 4.1 balun in the 986 is junk. I don't know! On 160 meters the internal 4.1 balun dosent get hot or even warm with a kw out. But I notice the BIG 1.1 gets a little warm with the same power out. I have also tried 450 ohm ladder line and really don't see much differance.
So what do you think 4.1 or 1.1??

Hello Larry,
After reading DX Engineering's technical info. on baluns
I purchased one of their 4:1 "big boys" - and think that it is the
best purchase I made for my loop. They have some good information on
their website ..
http://www.dxengineering.com/TechArticles.asp?ID={785E3CE7-211B-47E2-
A1DA-41A22BFD37ED}

just a happy Loop-er..
73 !

I have used one for 80mtrs.......

Feed point was short side, West end........

Live near Seattle, WA (Microsofts back yard).

On 80/40, did not seem to matter. Both bands showed very NVIS properties.

On the higher bands, best signal seemed to be on a broad arc from South-East to North-East. Could work North and South, but not as well. West was a very poor, overall. Hawaii and Johnston Atoll were OK, but beyond that, forget it.

When I am able to put another one back up, will be attempting to put in multiple feed points,
selected by relays, giving feed from East narrow end, South long side, and West narrow end as needed. Hope this will let me move the pattern to fill holes.

BTW...I feed my loop through a tuner and coax. I feel that gives less visual impact, very important here in this residential area.

Here is a link to an article dealing with the typical
"T" network antenna tuner and internal 4:1 Balun. This
article should answer all your questions.

1079. RJELOOP4, G4FGQ

Yahoo group: SkyWires
Date: 2005-03-28 20:39:17 UTC
From: Ron McConnell
Topic: 1079 Message: 1079

From rec.radio.amateur.antenna:

This new freeware program, RJELOOP4, by Reg Edwards, G4FGQ,
details below, should be of interest to SkyWires@yahoogroups.com.
Looks made to order.

<http://www.btinternet.com/~g4fgq.regp>

While you are at it, just go ahead and download
all of Reg's programs into a folder.

Cheers, 73,

Ron McC.
w2iol@...

Ronald C. McConnell, PhD

WGS-84: N 40º 46' 57.9" +/-0.1"
W 74º 41' 21.3" +/-0.1"
FN20ps.77GU96 +/-
V +5058 H +1504

<http://home.earthlink.net/~rcmcc>

Imagine if we had only Roman numerals for mathematics...
- RCMcC, w2iol

==========
RJELOOP4
This program predicts approximate performance of general purpose,
multiband, horizontal loop antennas of given perimeter of loop.
It is not intended for precision predictions of operating data.

A loop is a continuous wire without loading coil or capacitor.
It can be of any shape provided the area enclosed by the loop
is not less than 2/3rds of that of a circle of the same perimeter,
ie., it is not too irregular.

It is the sort of antenna which is forced on the amateur
by the shape of his back garden and the pre-determined location
of trees, poles, buildings or anything else from which an antenna wire
can be suspended.

Analysis includes a high or low impedance feedline, a choke balun
and an L-tuner. The antenna is most efficient when the perimeter
is a whole number of wavelengths. It is least efficient
when the perimeter is an odd-number of 1/2-wavelengths.

But operation is not limited to being at, or near to,
resonant frequencies.

Download in a few seconds program RJELOOP4
from website below and run immediately.

Regards from Reg Edwards

I don't believe that. The old system had body to it, it looked much
better. This system uses a lot more space that could be used for
something else. The old system may be gone but it will NOT be forgotten.

I usually read my mail in a mail client, so there is
no format change, but I went to the site to have a
look. It's not so bad. If you go to the messages
section, then click on "simple" as your view option,
it displays the same info as it always did in an easy
to read slightly larger font.

I like that you can sort the messages by thread now.
That is an improvement.

But hey, we all have opinions, right?
;-)

1089. First time loop user here.

Yahoo group: SkyWires
Date: 2005-04-07 13:51:21 UTC
From: wb9vwz
Topic: 1089 Message: 1089

Been reading this group for several months. Finally got up my first loop, a 20 meter version fed with 300 ohm RS tv twinlead, a 4:1 balun, coax to tuner hence to a 100 watt rig. Not as high as I would like (~20 ft) but it will have to do for now.

When I cut the antenna I intentionally made it about 5% longer (wire: 12 guage stranded insulated). With my tuner I can tune all frequencies from 20 thru 10. Don't know yet how well it transmits. It will tune 30 and 40, but I think it is probably an outdoor dummy load on those bands....

Now for my questions. Is it worth the time and effort to trim the loop for resonance on 20? Since I don't have one of those nifty MFJ units I have to use the old fashioned measure, trim, measure, trim routine. With the shack on the second floor it gives me a good workout.

I plan to build an 80 meter version later this summer installed from the roof peak (2 story house) to some trees in the backyard. The XYL is not favorable about overhead wires in her terratory so how small a wire can I reasonably use? Obviously, the smaller the wire the less visual impact and the less strength.

Thanks for your input, and if you hear me on the air, give me a shout.

Silky Wire is the smallest / strongest I have used, and I do like it (very hard to see yet very durable):

http://thewireman.com/antennap.html

Product nubmer: 520
'Silky' 18 AWG, 19 strand, tinned, 40% copper-clad steel. popular as a portable easy-to-use dipole wire.
Prices: Per Foot= $0.11; per 100-ft $0.09; per 500-ft $0.086; per 1000-ft $0.081

On the other hand, I have #14 stranded copper up for my loop. After a short time it tarnishes and is very diffucult to see, but somewhat easier to see than the silky. I have generally had the to point it out to people, and even when I'm looking up to verify it is still up, even _I_ have a trouble finding it at times!

I'd not bother tuning the wire myself. But I'm lazy and use a tuner ;)

Erik,

Just curious- I have been interested in the Silky Wire. My concern though, how strong is it (Pull Strength)? I presently am using 18AWG (bought it cheaply as an experiment) and it is not sufficiently strong for me. This is for ~ 1000 ft. Loop. I realise
that 14 AWG would be better, but is also more expensive. As much as like FLEX-Weave, the cost at that length for insulated is about USD .171/ft !

I've not used it over the size of a full wavelength 80-meter loop (roughly 280 feet). Certainly not 1,000 feet length.

As for as foot-pounds of pressure until it breaks I'd suggest you ask the Wire Man, I have no idea. It says it weighs less than one pound for 1,000 feet so I don't think it'd have very much stress on it, even at 1,000 feet.

Don't think that helped much, sorry.

1096. how much windload??

Yahoo group: SkyWires
Date: 2005-04-10 04:28:44 UTC
From: chasm@texas.net
Topic: 1089 Message: 1096

does anyone know how much windload the ALPHA DELTA DX-CC dipole presents???
am wondering just how strong my end poles/masts/dacron ties need to be esp down here in Houston.

in fact, is the amount so negligible that it is virtually never shown for any dipole or sloper??? but is for beams, etc...

I have similar questions for Windom's...

thanks
chas

1097. Static bleed off

Yahoo group: SkyWires
Date: 2005-04-14 00:41:27 UTC
From: cloud_burner77
Topic: 1097 Message: 1097

Hello everyone, I would highly suggest with a loop antenna, to
install
in the feedline an arrestor to bleed off the static and protect from
lightning. Static bleed off is not talked about much and can be very
dangerous. I use a devise that can be found at www.arraysolutions.com

1098. Re: [SkyWires] Static bleed off

Hi Group,
I found Static and Surge Suppression Inductors at
http://www.arraysolutions.com/Products/staticsurgecoils.htm#top%20of%20page

for $35.00 each or a person could very easily wind their own . Although these are for Large vertical antennas such as any 160 meter full sized vertical.
Any loop antenna is already at DC ground potential so static bleed off should not be a concern .

I have 2 web pages that mention the Static problem.
http://www.bloomington.in.us/~wh2t/invertedl.html

And

http://www.bloomington.in.us/~wh2t/Jpole.htm

They give the following info.

IMPORTANT NOTE:
End fed wire antennas can develop very high static voltages on them.
This static voltage can easily be high enough to knock the front end out of sensitive receivers.
To overcome this problem, I suggest you connect a resistor from the coax center to shield where the antenna wire connects to the coax.
Only use a non-inductive resistor, carbon resistors work fine.
Don't use wire wound or metal film resistors.
The resistance value is not critical.
I suggest about a 56K ohm 1/2 watt resistor for receive only or if transmitting with up to 100 watts.
If you will be transmitting with high power "QRO", I suggest using about a 1 Meg ohm 1/2 watt resistor.

IMPORTANT NOTE for SWL Receivers:
End fed wire antennas can develop very high static voltages on them.
This static voltage can easily be high enough to knock the front end out of sensitive receivers.
To overcome this problem, I suggest you connect a resistor from the antenna wire to ground near the back of the receiver.
Only use a non-inductive resistor, carbon resistors work fine.
Don't use wire wound or metal film resistors.
The resistance value is not critical.
I suggest about a 56K ohm 1/2 watt resistor for receive only or if transmitting with up to 100 watts.
If you will be transmitting with high power "QRO", I suggest using about a 1 Meg ohm 1/2 watt resistor.

1100. SHORTWAVE RADIO ANTENNA ..PERFECT FOR LIMITED OR RESTRICTED SPACE 4 SALE

Yahoo group: SkyWires
Date: 2005-04-14 02:34:11 UTC
From: peanutpaster
Topic: 1100 Message: 1100

Hi I make and sell a shortwave antenna on ebay called a super helical.
The
antenna works really well for the ammount of space it takes up. It is
roughly 65 feet of wire but when set up only takes up about 7 or 8
feet of space. It is perfect for indoors and can be hidden. You can
read more about it and check it out on this link. If no listing
appears check back soon for I list these often.

Thanks for this info.

In these references, and in my thoughts, this situation will not occur with a loop antenna since it is a DC short, or nearly so taking wire resistance into consideration. In the case of open ended, long wire, end fed, or what ever terminology is used to describe an antenna with a center radiating element which is a DC open to ground this static buildup would occur and be a problem. With a loop antenna this would not occur and would not be a problem, one of the reasons a loop is known to be a low noise design. Anyone think otherwise?

Be careful here, my 450 ft double loop has knocked me to the ground several times last year when I unhooked my ladder line and touched the ends accidently, its like being hit with an electric fence, If you dont think loops have static ask w6obb and all the otheres who lost icom pros in the recieve mode due to static. This device from Array solutions keeps the loop DC grounded at all times, but important here, if your running high power over 600 watts be sure to order the model to handle higher power and the cost is approxamently $72.00 for that model. Thanks everyone, Cloud_burner77--- In SkyWires@yahoogroups.com, John Isella <jjisella@c...> wrote:

Topic: 1097 Message: 1103

My loop enters the shack through two threaded 1/4 inch steel rods inside two pieces of pvc tubing. I normally keep a 350 ohm resistor (nothing special about the value, just something I had on hand) bridging the loop when not in use.

Without the resistor, I've been able to draw arcs during a snow storm from the loop to a nearby ground (using an insulated screw driver and a clip lead). All from static buildup.

The loop may be balanced but can still collect a static charge. If your rig is connected than the charge will discharge through the receiver front end.

A couple of years ago I observed a very interesting thing. I had a clip lead shorting the loop where it enters the shack. Every once in a while, the clip lead would swing toward an outlet box mounted in the wall nearby. Turned out to be an approaching thunder storm that I hadn't heard. The clip lead moved in time with the lightning strikes.

That's why I ask, lets talk about the details here so we all gain a better understanding. My thoughts are that with a system that has a loop antenna where the antenna is feed with one side grounded, at a tuner for instance, there should not be any significant buildup on the loop. When you disconnected the antenna how long was it floating prior to your touching it? What were the configurations where these other folks had damage to their rigs? It sounds like the feed configuration you are talking about result in the loop floating or in any event not grounded at one side. Is this correct? If it is, where perhaps a tuner is used which couples the loop in such a way that the loop is floating then I would agree in concept that you would get static buildup.

I think otherwise .... hi. I have seen 6" sparks drawn off the feed line (open wire) which feeds a rhombic antenna ... which is a kind of horizontal loop.

Well, lets see ..... take a 1000 ft of wire and suspend it above the ground. Wait for the right environmental conditions .... some thunder clouds in the near distance, some wind, some dust, etc .... and the wire will become charged in relation to the earth and it will be possible to draw sparks as long as 6 inches between the wire and ground.

Now, join the ends of the same 1000 ft of wire suspended above the ground to form a loop and wait for the same environmental conditions. The loop will build the same static charge more or less as the straight wire.

The question is, will the static charge be dangerous to your equipment? The answer depends on how you connect to the wire (feed the antenna). If you you feed one end directly to your radio the charge will find its way to ground through some circuitous route with the potential for damage. If you break the wire in the middle (a dipole) and feed it directly with coax. then one half of the wire will be at DC ground potential and the other half will feed directly to your radio. This is the case with the 1/4 wave vertical as well. With the dipole most people feeding with coax will use a balun which will put both sides at DC ground. However if you use a current balun formed by coiling the coax you will not get this benefit of DC ground!

Now instead of configuring the wire as a dipole, join the ends to form the loop. Now the entire wire will be DC ground when fed with coax. The only reason now to use a balun will be for purposes of 'balance'.

Now if you use open wire feed line and terminate the line in a 'link' then the whole antenna is isolated from DC ground. I would not bring my finger

too close to the feedline/link when there are environmental static conditions, regardless of whether the antenna is a dipole or a loop!

PS

Back in the dark ages our solution to the above situation was to use common auto spark plugs, one connected on each side of the open wire line to ground. We also had a huge knife switch to put the feedline directly to ground when electrical storms were close. When environmental conditions were very bad .... eg a dust storm ... the plugs sounded like they were in a car; "snap, snap, snap, snap" . If they were in my motorcycle I would be going 50mph hi hi.

If you use ladder line and the 4:1 Balun in your
antenna tuner or even an external Balun and you have
the Balun properly hooked up to ground like you should
be doing anyway the static will be draining to the
earth ground constantly. A neon bulb from the link
coil to tuner ground will not effect the operation of
the balanced antenna tuner and will drain off the
static as well. As for feeding with coax, if your
station is properly grounded then your loop is also
grounded.

At the club, we call it "Blue Lightning." I've seen some pretty dramatic flashes from our dipoles, windoms, end-feds, etc. during almost any kind of weather condition. Windy days and dry snowfalls seem to be the worst, but not exclusively. Think about a wire antenna as the secondary of a transformer...just sitting there in an electro-magnetic (or electro-static) field absorbing energy. Antennas are transformers that do not discriminate between radio signals and Natures energy.
At one time or another, ALL of our wire antennas have bit one of the operators...that's usually followed by some words we learned in our adolescence.
ALL of our antennas are now connected to metal, GROUNDED, boxes that have the following:
1: a 50K ohm, or higher, carbon bleeder resistor
2: an NE-2 neon gas tube
3: a fairly heavy toggle switch (for non-use times)
BTW: I use steel surface mount electrical boxes with blank plates for the switches and a brass stud for the ground connection.
But...there's another advantage to grounding wire antennas when not in use. When there is an electrical storm in the area, it is very advisable to NOT have anything nearby which can develop a charge. In lightning pre-strikes, the plasma leaders and streamers and very happy to find items on the Earth that have pre-existing charges on them. The likelihood of the REAL strike following the path to the charged item is greatly enhanced under these conditions. When your antennas are completely grounded...it is somewhat like placing the area under them (your home?) below (electrical) ground and actually protecting (somewhat) the area below (cone of silence???). It's not an absolute thing, but certainly a step in the right direction.

If you use ladder line and the 4:1 Balun in your
antenna tuner or even an external Balun and you have
the Balun properly hooked up to ground like you should
be doing anyway the static will be draining to the
earth ground constantly. A neon bulb from the link
coil to tuner ground will not effect the operation of
the balanced antenna tuner and will drain off the
static as well. As for feeding with coax, if your
station is properly grounded then your loop is also
grounded.

In a loop fed direct with coax by a grounded radio, yes.....the loop is at ground potential though the shield on the coax.

From what I have seen on lists, most are feeding their loops with bal feed line through a tuner. Many systems keep the entire feed line and loop isolated from ground. This can let a massive charge potential to develop. Steps must be taken to remove the charge to prevent damage to radios and other equipment.

There are bal tuners that maintain a ground on the feedline and antenna. Depending on how they do this, the system could still develop a dangerous charge potential.

I feel that you must look at your situation and your true risk. If you get lots of electrical
activity in your area, make sure to provide a path to ground and disconnect the feedline(s) when not in use. In areas with very little electrical activity, you may be able to get away with
just providing a bleed path. If in doubt, disconnect and ground your feedline.....best idea any
way.......there is no such thing as being too safe......

Again DC Chassis Ground is not and never will be the same Point out of the box ! ! ! !
Take your radio off line completely. Unplug it disconnect everything, just like when you rook it out of the box for the first time. Take an analog VOM ie Simpson 260. Switch to ohms R x 100 Position. Measure across Case/chassis Ground to the center conductor of your SO-239, BNC or the appropriate leg of your balanced feedline terminal. Now switch your leads, If you see DC short in both directions your radio did not work in the first place. Please post the results of this very simple test for all to see.

You are missing what is being said........

In the case above, you HAVE NO ANTENNA......Yes, with no antenna, there is no path to ground from the center of the connector......Check between the barrel of your radio connector and the radio ground connection....should be an almost perfect short, right? Well,
that ground connection goes to your ground rod.......or it should if you have your station set
up correctly.....

Now, look at a coax feed loop antenna....it is basically a short across the antenna connector.
If you check the same points you talked about above, WITH THE ANTENNA CONNECTED,
you should measure a resistive short.....the resistance of the wire used to make the loop, and the coax.

Baluns, tuners, ect may change this....example: a link tuner has no direct connection from the radio to the antenna...it uses coupling to pass the RF.

But, if you look at the antenna, there is a direct path between the antenna feed point to allow
a charge to pass....as long as this direct path is maintained to the radio ground....direct feed
with coax will do this, a balun or tuner may not.

All well and fine! but the !00,000 volts does not travel down the braid or go to the barrel on the chassis it travels down your wire or radiator then to the center conductor to your front end. One must bleed this off one way or the other. Spark plug, Commercial static arrestor or a hand built 100uh or so RF invisible static choke from your center conductor/radiator to ground. Then and only then will you have an true RF/Chassis ground for DC static buildup. . Tune in a station and then hook up the wire choke, you will see no change in your signal on rcv. or transmit if you do transmit. But then take the Simpson and measure the same points I mentioned, WoW as if by magic, Center Conductors to RF/Chassis Ground. DC short to RF and to Chassis ground but it still can hear with no degradation whatsoever of the received signal. If you see any downturn in signal strength you need more turns. Same theory is behind feeding 5K Vdc to the plate of a tube. Big wire choke between the tube and the transformer/Power supply etc. but the RF output from that same point of connection does not see the Power Supply, it will see only the loading circuits and then the antenna.
Solid state amps do the same thing. The Collector Voltage on a class C FM amp is the same Place the DC power goes to. Put thru a correctly valued coil/Choke the RF out of the transistor does not see the power supply.
Direct hits in my backyard so close I can smell the ozone and all my fronts ends still work, DX100, DX160, DX 200, 384, Panasonic's 4800 & 4900, Sat. 800, R75, Drake 2-B, AOR AR 8000. Sony Air-8, Sony ICF 80/RFQ80, Panasonic RF's 1600, 1700, 2900 Hitachi World Space KH-WS1 Plus about 25 different Scanners Starting from The Electra/Bearcat III to The Radio Shack 2006. Tranceivers to include Icom 251A, IC 726R. Yaesu 102, Swan 250C, Vertex VXA 700 Aviation HT. Last but not least 4 Motorola Maxtracs set up with P. Supplies as Base Radios on 146, 450 and 900 Mhz and they all have their ears on and are listened to and transmitted with virtually on a daily basis. So If I am missing something good for me. If something is missing me for the past 25 years, I am sure it is due to what I do to protect this motley assortment of radios and I will continue on my merry way for sure for another 25 years no doubt about it.
In conclusion: there are way too many variables in equipment and setups to say well your ok if you do this and this, if you are using this tuner with feedline type X to antenna type blah blah with Balun xyz at the feedpoint or in the tuner.
Always, Always, Always provide a direct RF/Chassis DC ground and you will never be in doubt or trouble, Period.

To the other list users...sorry....very sorry....very, very sorry....this will be the last post on
this by me to the list.....enough is enough is enough is enough.....

To Mr. Conover.....A LOOP IS A SHORT TO GROUND, AS LONG AS YOU DO NOT
INTERRUPT THE PATH WITH A BALUN OR TUNER THAT WILL NOT PASS THE
CHARGE AND YOU HAVE YOUR RADIO PROPERLY GROUNDED!!!!!!!!!!!!!! A CHARGE
WILL AND DOES FLOW ON THE BRAID AND WILL FLOW TO GROUND!!!!!!!!

Pick up a copy of World Radio, April 2005 (year 34, issue 10) and look on page 10. An article by Steve Cerwin, WA5FRF on the Loop Skywire (he calls it The Long Wire Loop).

"The antenna has a feed point that presents a short at DC for elimination of static buildup and rain noise and also provides excellent rejection of out-of-band signals, giving very quiet
receive performance."

Elsewhere, he states....."The loop appears as a short at DC and has a low lightning profile compared to a tower, giving some measure of lightning protection. The combination of the DC short and harmonic resonant nature of the long wire loop minimizes out-of-band noise pickup, making the antenna very quit on receive."

1120. Re: [SkyWires] suggestions for small yard with restrictions

Yahoo group: SkyWires
Date: 2005-04-15 21:06:31 UTC
From: charles allison
Topic: 1120 Message: 1120

Hi all,

One of our friends has just had to move to Houston and wants to get on the air. They may have some deed restrictions on antennas and their back yard is perhaps 70 by 30 feet. We are trying to see what we can come up with in the way of a low NVIS type of antenna for 80m and 40m and hopefully higher bands too. He runs 100 Watts and would like to communicate with friends within about 250 miles. I would like to put it about 6 feet up around the fence and then onto the roof or edge of the roof to minimize visual impact in case of any restrictions.

I'm considering doing a loop, preferrable 1 wave length if possible, out of 14awg stranded insulated wire from the local Lowes. I have some new 450 ladder line available and have Dr. Ace's 4:1 home made balun instructions and construction materials. I also have a 4:1 commercially made low cost voltage balun. My construction approach requires making screw terminals for the wire/ladder line in case there are some trees there. If there are, we might be able to string the antenna up into them some - assuming they are more than 6 or 8 ft tall. It might have to be 1 wavelength at 40m and just tuning for 80 but 80 will be of most interest.

The basic layout will be to bring down the ladder line from the edge of the house to the balun and a ground stake. Soil there is gumbo muck - they are almost in the flood plane of an old muddy river, the Brazos. Windows are aluminum so I expect we will have to run coax through the wall rather than bringing in ladder line. Installation time will need to be minimized as I and his other friends will not be able to be there very long.

He will have to buy a tuner. probably a low cost mfj.

I don't know what the typical wiring speed of light is but I'm going to assume it will be about 92% or 95% resulting in a shortning of the loop rather than 1005/F. Normal operating frequency on 80 m is about 3855khz.

I would appreciate any suggestions on approaches or 'gotcha's to watch out for. I might be able to set up the antenna here and check it with an mfj 269 analyzer but there are problems in doing that here before I go.

best regards,

Charles

I'm certainly interested in what you manage to come up with. I currently am in a new gated community with _strict_ regulations. We bought into this place before I realized we'd be getting back into amateur radio. To make it more interesting I'm one of the members of the Architectural Control Committee so my property gets serious scrutiny by everyone who doesn't like the rules that we're enforcing.

I really need a low visual impact HF antenna. <smile>

A full size 40-meter loop requires 140 feet of wire
and would easily fit in your back yard. As for wire, I
would get a small roll of aluminum electric fence wire
and enough of the insulators to install the fence wire
to the top of the fence. I am assuming it is a wood
panel privacy fence. Put the wire on top in plan
sight. If nosy neighbors ask about it just tell them
its part of your burglar alarm system. They will
believe you in an instant, as there are systems that
include wire fence sensors as a part of the burglar
alarm system. You can get away with running that fence
wire around the front of the house as well if you run
it around the roofline. Just tell it also detects a
ladder placed on the side of the house. In that case
you may be able to install a full size 80-meter loop
with 272 feet of wire. The reason to use the electric
fence wire is that it's the same stuff used on burglar
alarm systems guarding a fence. If you can't get the
loop out of the back yard place a switch opposite the
feed point of the loop. Opening this switch will allow
you to load the 40-meter loop up on 80-meters.

Hi Mark,

If your property is a house or a side-by-side type unit that has a roof that provides some attic space you might want to try a 'hi-capacity' antenna. I am going to try building one this summer in the attic of my garage; more out of curiosity rather than necessity. The antenna has some very interesting characteristics:

- Small ... 6'x6' base and 3' tall for 20M
- High efficiency!
- Very little electromagnetic interaction with metal objects (minimal RFI)

The Gap Antenna Co. markets one (20-17-15-12-10) called 'SuperC' and has a lot of info on it and the theory behind the design on its Internet Site. It sounds like the kind of antenna that provides both a low visual and RFI profile. Your AC Committee certainly wouldn't see anything ... hi hi.

Topic: 779 Message: 1131

Traveling to the US in a few weeks and wonder if anyone can tell me the name/location of a home building supply/hardware outlet where I can pick up some decent quality 2/2.5 inch plastic/nylon pulleys for my loop. I'll be in the northeast area as far south as Maryland and as far west as the NJ/PA border.

Thanks,
Dave

We have a lot of marine/fishing supply places here in Nova Scotia but all of the pulleys I've seen are larger and much heavier than what I need for the loop. Usually made of stainless steel (hence the weight).

Wanted a half decent one made of nylon or some such material. Saw some made by a company in CT some years back but can't remember the mfg's name or where I saw them. Even spoke with the manufacturer about a Canadian source (nothing at the time). Tried a GOOGLE search but nothing found.

This will give me a excuse to stop at every home supply/hardware store that I see along the way.

1142. Feeder as vertical radiator

Yahoo group: SkyWires
Date: 2005-05-18 17:02:30 UTC
From: subriaus
Topic: 1142 Message: 1142

Hi
Just joined the group and pleased to see so many using the loop.

I am using a 80M skyloop abt 20Mts up feeding it with 450 Ohm to a balanced Z-match and it´s a terrific antenna.

On lower bands it´s more of a NVIS antenna although 40M DX is doable. Read in the Antenna handbook thats it´s possible to use the feeder as a vertical radiator on the lower bands with the loop as a capacity hat.
I have tried with some ground radials as it looks good, but question is this.I am able to get a good load on lower bands

The feeder enters the shack via a window to the turner. The feeder acting as a vertical radiator has a power of some 400W and this does not sound healthy at all, sitting a few feet away from it.

So how do I come up with a solution to run the feeder to a remote turner that can tune both balanced (for the higher bands) and a "GP" style on the lower bands.Was thinking of running coax from the remote turner to the shack.
Or is it safe to use the feeder into shack.
Anyone tried this ?

Thanks
Frank

Hi Frank,

If you feed the loop as a balanced antenna with open wire feed line there will be negligible radiation from the feed line. The only problem you will have is simply mechanical in getting it through the wall or window to the operating position and your z-match. The second consideration with this installation will be grounding for safety in case of electrical storms etc. RF in the shack will not be a major problem ... even with 400W output.

However, if you decide to use the antenna as a vertical fed against ground .... eg. tie the feed line connectors in parallel and treat the whole antenna as a top loaded vertical you will indeed have RF in the shack area. This will work well with 100W. ..... however running 400 watts my liven things up in the shack hi hi.

I used a similar system many hears ago. I had an inverted V antenna on the roof of a second story house. The feed line was 300 TV twin lead going

down to the shack in the basement. I used the antenna in the normal balanced arrangement for all bands except 160M. On 160M I feed the antenna as a vertical .... 60' of feed line to a 100' inv erted V on top. I used a water pipe in the basement as ground. With this arrangement I participated in a morning round table on 160M with no problem ... running 100W AM.

Keep the tuner as close as possible to the entry to the shack and provide the best possible ground system. Whether you can get away with 400W output is something else.

Good luck

1144. Help with Delta Skywire

Yahoo group: SkyWires
Date: 2005-05-20 07:50:58 UTC
From: verbli
Topic: 1144 Message: 1144

I am trying different antennas at my QTH and has arrived at the Skywire.

I would like the antenna to cover 80m and up. I have only room for
abt. 60m in a delta shape. (3x20m) The antenna will be installed at
10-11m above ground at one corner, but the ground slopes a little so
at the two other corners the hight is 7m above ground. The feed is
with homebrew ladder line at abt 550ohm or standard 450ohm line. Tuned
in the shack. The three supports are already there, but I may be able
to widen/extend it some by putting up another support

My questions are:

Would I be able to tune this antenna without to much feedline loss at
80m? What loss figures should I expect?

Will it have less noise pickup than a doublet?

How will it perform compared to a doublet (abt G5RV size)?

Thanks in advance,

Verner

Verner,
The preferred skywire shape is one that encloses the most area: a perfect circle is best, but a horizontal delta should perform OK for you. I started with a delta for 40m, but then figured out how to add a fourth support. Actually, I started with an end-fed Zepp, then a doublet, then a Delta, then the four-corner Skywire.

I did not notice a significant improvement on the fundamental band when I added the fourth support to the delta loop, but I noticed the performance on the upper bands was much improved. Since it's a loop, the noise pickup is much lower than a doublet. I use my 40 meter loop on 160 through 10 meters - it's the best antenna I've every played with.

One of the math professors on this list may be able to help with the loss calculations - I am more of a cut-and-try engineer. I know that balanced open wire/twin lead is lower loss than coax, and my setup (300 ohm twinlead) works well.

Jim, thanks, I put up the delta today.

Have not had the chance to QSO yet, but it sure sounds promising on
receive. My noise is down by abt. one S point compared to my doublet.

Will get back with more of my findings later.

Jim, do you just tune it up on the lower bands or do you feed it as a
vertical?

Thanks,

Verner

1148. Re: [SkyWires] Re: Help with Delta Skywire

Yahoo group: SkyWires
Date: 2005-05-22 04:13:17 UTC
From: JimMcSkate@aol.com
Topic: 1144 Message: 1148

Verner,

I tune the antenna on the lower bands by driving ONE LEG of the feedline and leaving the other leg open. I drive this configuration against a good ground. I can never be sure of how much power is radiated from the feedline, and how much from the loop itself. My tuner easily matches this to unity on 80m, and to about 3:1 on 160m... I run a 29 year old Kenwood with 6146B tube finals, which has no trouble with higher SWRs.

The "standard" way to use a Skywire Loop on the lower bands is to short the feedline legs together and drive the antenna like an inverted L vertical. In my experience, this put a LOT of RF in the shack, into the house telephones, into the baby monitor, into the toaster, etc. Driving one side of the feedline somehow balances the equation and puts the RF into the air instead of into various household electronic devices.

Glad you got your Loop up there... I hope you have great luck with it!

Greg,
Just follow the "largest enclosed area" rule and you should be OK - if you are fortunate to be able to add additional support(s) to round out your delta it will help. The supports don't need to be much if you build lightly - a piece of monofilament fishing line tossed over a treetop can serve to pull your delta into more of a loop. A funny-shaped loop that encloses the most area you can get will work just fine. Of course, funny shapes have radiation patterns that are harder to model using ezNEC on your computer, but last I checked, the ionosphere doesn't use ezNEC.

By the way, I am using cheap-o hookup wire - 18 or 20 gauge stranded insulated wire, Radio Shack 300 ohm twinlead, and it's survived two nasty New York winters and gets out better than the tribander I once swung.

I am very impressed with this antenna design, in no small part because it's a delightfully inexact science. Oh, and because it's stealthy. And also because it really works.

73, & hope this helps...

I had a 160m loop that 'pinched' in the center, at one point only 45 feet apart. Must have looked like a 'bow tie' from the sky. Worked gangbusters on 160, and was noticably directional on the lower bands.

Great group, thanks for making it open. I've always loved loops, and I just recently put up another one for 20m. It's a monobander, fed with coax into a 2:1 commercial balun. It's triangular, fed at the apex about 35 feet with the bottom section horizontal at about 15 feet. The antenna actually acts as two of the guy wires for a push-up pole.

The match is unbelievable and I can hear things I never knew were out there. When I first hooked it up, I thought something was wrong because there was no noise level. I turned up the volume to hear the 'static.' Then when I tuned a little and came across a signal, it almost blew my ears out.

I would encourage anyone to put up a skywire loop or loop of any kind!

Jim,

What do you do with the other feedline end? Is it just disconnected at the tuner in the shack?

Have had several QSO's on my loop now. It seems compareable to a doublet on the bands I have tried, or maybe slightly down. BUT it is quieter so currently I feel it is more useable for me than the doublet. I'll keep it up a while and see. Not had any qso's on 80m yet. But local (North Europe) incoming signals are good. But how (if)I get out with only 3x20m on 80m, I dont know yet.

Verner,
I connect one leg of the feedline to the tuner, and leave the other leg unconnected. The tuner and transmitter are well grounded, using two 2 meter grounding rods plus a cold water pipe. I have tried to short both feedline legs together, which is the common way of driving the feedline as a vertical with the loop as a capacitance hat, but I had little success with this configuration... there was a lot of RF in the shack (received burns off the knobs of my rig) plus many electronic devices in my house (phones, television, etc.) were affected.

For a diagram, see www.qsl.net/wa2lgn. (I realize I need to update the page... I am still bald but my children are a year older now!)

Earth ground is a electrical safety ground, it make a very poor
counterpoise. The counterpoise should be hooked up at the antenna feed
point, a choke balun will also help keep the RF from coming down the
outside of the coax and into the shack.

Jim,

Yes, I get the picture now. Had a look at your web site too.

Also I have tried the 3x20m delta skywire on 80m. It goes out well enough. I was well over S9 last night on a local (300km) qso (100w). That was the same as the guy I worked, he used a dipole. I was worried that I would loose to much in the feedline due to SWR. But it seems to be useable without running it as a vertical or random wire.

So I'll stick with it for a while.

Now I'll have to find out where to put the feed point for maximum coverage to my prefered areas (DX). Also I may put up another support to open up the loop a bit more and possibly add a few meter more wire.

Thanks,

Verner

In the end it is whatever works. Years ago I had a basement station ....
in fact I have had several hi hi .... In this particular station my
operating position was in the basement. I had a 30' pop-up TV mast mounted
at the peak of the 2 story house. The mast supported the center of a 100'
inverted Vee fed with 300 ohm TV twinlead. The twinlead came down the side
of the house to the basement window. I fed the whole thing as a vertical
on 160M using the hot water heating pipes as the ground/ground plane.

The system worked like gang busters with 100W AM. Checked in to a farmers
160M early morning net (after milking the cows I guess).

Hi all,

About a month ago I asked for suggestions for doing a stealth loop for a friend living on a small lot in an antenna restricted neighborhood. I was intrigued by the suggestion to use electric fence wire and standoffs so as to be able to claim it was part of a fence or security system sensor as well as to be invisible from the street.

We ran 17ga aluminum fence wire under the eaves of the house about 8 ft off the ground. The total length was in the general vacinity of about 250 feet. We kept it about a foot from the house edge and about 6 inches from the various sections of metal gutters. At the back of the house by the ham shack we used a center insulator made from a scrap of 1/4" plexiglass with two 1/4-20 bolts to hold the wire and the 450 ohm feed line. The feed line was about 12 ft long and went over to a 4:1 balun and coax. We also put in an 8 ft ground rod at the coax entrance to the house and used 8" so239 barrel connector through the wall at the edge of the window.

While the loop is intended to handle all hf bands and be general purpose as the only antenna at present, most of the use is for a small 80m early morning regional net composed of a few mutual friends who meet every weekday morning.

We use a 15ft high 80m loop as an nvis antenna along with a g5rv inverted vee for regional communications on 80 and 40m.

Since we installed the new stealth antenna for our friend, most of the net days have been bad to very bad with a few being very good. So far the new stealth antenna, located about 200 miles to our north east has been doing better at communicating with us than the others located about 150 to 300 miles to our north. Today, it even did better than another local ham located 20 miles away which usually has the best signal. Conditions were so bad today that we weren't even sure if someone else was in there or not and none were armchair copy as when conditions are ok to good.

Net results are that the 80 meter stealth loop is not only virtually invisible but it is functioning rather well. It is even surpassing more conventional antennas in performance for it's primary use. It's far exceeded our hopes for a usable functioning antenna. And the net expenses were under $25 for everything except the old 4:1 balun which was one of the least expensive commercial ones available when it was new.

Thanks guys for the suggestions and if you encounter similar requirements, don't hesitate to try this approach. It can work well.

best regards,

Charles

Well I have up a horizontal loop about 312' long and am pleased with the results so far. My problem is getting all the balls in the air at the same time so to speak. I have hooked up the radio to a coax to a ten tec 227 tuner. Then about 12' out the window to a choke. It has approximately 20' wound around a paint can and taped, placed up under the eve of the roof about 12' off the ground. Paint can removed. The 520 has the plate, load, and drive knobs plus I am dealing with a tuner and a SWR meter with 20W, 200W, and 1kw
readings
My problem is that I thought that when you tuned a tuner that you were suppose to hear a louder sound coming from the speaker when you got close to tuned. I realize that the longwire has quieter sounds. Not as much noise as with other antennas. I would appreciate any help anyone could give. It seems that the load is set at different places for different bands but I'm not sure if I am putting out the full wattage the radio will do or not. When I get the meter set and broadcast the needle on the cross hair needle is on the bottom. I'm a new ham and a new General. It is probably me and the radio and the learning curve I'm having with the radio not that it isn't working. Thanks 73s Ed KC9GYI

Hi Ed,

The way to deal with 'all the ball in the air' is to first look at them one at a time and learn how they work. The 'balls' are 1. TS520 xcvr 2. SWR meter 3. Antenna tuner and last but not least, 4. the antenna.

1. The TS520 is designed to feed a 50 ohm coax line connected to a 50 ohm load. The easiest way to practice tuning (adjusting the plate, load, and drive) is to connect the output to a 50 ohm dummy load. The 520 output is in the 100 watt range (be happy with 50-60W). The plate is always adjusted for minimum plate current and the load and drive carefully adjusted for output. So, get a dummy load (buy or borrow) and practice. Jot down the settings for your favorite band/frequency.

2. Now connect the TS520 to the dummy load via the SWR meter. Your meter has 20,200,1000 watt ranges. Set it to 200W and you won't have to change it again unless you get a linear amplifier and increase your output. Now learn how to set and read it for SWR .... which should be at 1.1:1 when you feed the dummy load.

3. Now connect the TS520 to the dummy load via the SWR meter and tuner. Now practice adjusting both the 520 and the tuner for the same output power level and xcvr settings.

4. Now, after you are thoroughly familiar with the way each of the units work and are adjusted you can remove the dummy load and replace it with the antenna. Ideally an antenna fed with 50 ohm coax should represent a 50 ohm resistive load, or close to it. If the antenna is a lot higher or lower in impedance there will be a high SWR and you will experience losses and your TS520 won't be too happy. The objective of the tuner is to correct this mismatch to a level acceptable to your XCVR. As a general rule of thumb your SWR should not be higher than about 2:1. The tube amp in your 520 is more forgiving than more modern solid state amps and you might be able to operate at 3:1 (but cut the power output to no more than about 25w output under these conditions).

If you can't get 2:1 or at least 3:1 on the SWR meter then you will have to work on the antenna.

Have fun practicing Ed

73 Jim

PS You can't tune by 'ear'. The SWR meter is for this purpose.

This message is for Jim and Ace.. Wow, I wish I had you guys to answer questions like this one when I first started.. THe 520 does have a learning curve. It took me a while to get everything down but as Jim said it is a very forgiving radio. I miss mine now it sounded better then any rig I've owned to date. Once you tune it up a few time it becomes very easy to do plus tubes are way cheaper then solid state finals.. Hope you enjoy the 520.

Hi Ed,

The SWR meter you have measures forward power and reflected power. The SWR is the ratio between the two. You try to get it as low as possible .. eg less than 2:1. The problem with this approach is that your adjustments have to be made 'live' eg with power transmitted. If you use an SWR bridge, also known as a 'noise bridge' it is possible to adjust the antenna tuner with no power being transmitted.

The noise bridge has an internal means of generating low level noise across the whole HF and VHF spectrum. It has a couple of dials that you can adjust to balance out the noise to its lowest level 'by ear'. You can then read the dials and they will tell you the impedance of the antenna and whether it is inductive (too long) or capacitive (too short). The bridge is not a device that you use a lot unless you are someone who does a lot of experimenting with antennas or other circuits.

The bridge will have 2 connectors .... one for the antenna and one for the receiver. In your case you have a transceiver .... you must be very careful to use it only as a receiver when you have the bridge connected. If you should press the PTT button on your mike you will almost certainly blow the delicate components in the bridge. In short, a bridge is a 'passive' device used primarily while you are designing and building your antenna. Once the antenna is satisfactory you remove the bridge and connect the SWR meter, tuner, antenna setup to the transceiver and monitor your transmissions with the SWR meter. The bridge will be in the drawer most of the time.

Here is an example. Say you want to transmit on a particular frequency on 75M .... a local net perhaps. Tune your receiver to that frequency. Turn on the noise bridge and you should hear an immediate increase in the background noise. Set the resistance dial to between 50 and 75 ohms and the reactance dial to 0 (eg no inductive or capacitive). Now adjust your antenna tuner to reduce the noise to zero or as low as you can.

Now remove the bridge from the circuit and put in the SWR meter. The combination tuner/antenna should be an acceptable load for your transmitter. Before removing the bridge you should do the same thing on all the frequencies and bands you want to operate. The best strategy for

someone starting out is to design the antenna for a particular band then go on from there.

Jim

The TS520 has a "tune" function (on the mode switch on the left of the panel) which puts 5 or 10 watts out the back. I set the switch to "tune" then flip the "send" switch to both tune up the radio AND to set the antenna tuner. This way you can spend some time tweaking without worrying about toasting your finals.

You'll find that the tuning of the transmitter is affected by the tuning of the tuner, so it takes some time to get the "hang" of it. Now, I can tune the whole setup in a few seconds - just took some practice.

Best of 73,
Jim

One more thing to add; after you have done all the other suggested items (all excellent, by the way). You can REPEAT the entire tuning procedure on the Kenwood. If the antenna tuner only brings you to a 3:1 or so SWR, the output network in the 520 will act as "another tuner." You may even be able to load the old girl into your antenna on several bands with NO external antenna tuner in line at all. The Old Timers did it all the time.

Glad to see another loop user!! AND 520 user!!!!!

My brother had a 520S and I had a 820S...I still have my 820S. Good radios....just can't bear the thought of getting rid of it - even though I now have an ICOM 756Pro. The 820S was responsible for my DXCC and WAS.... Both are excellent rigs to learn and use. Audio quality is excellent, and really enjoyable...

Thanks for all the help. I am making some contacts. I worked a guy in L.A. this morning from Indiana. Wasn't a strong contact but we both got each others call signs while the band was in.I'm going to use these suggestions and learn tune this rig and get out. I'm real pleased with the radio and the antenna, especially the stealth part of it. 73s Ed

1168. Using 75 ohm coax

Yahoo group: SkyWires
Date: 2005-06-05 20:31:52 UTC
From: Hal
Topic: 1168 Message: 1168

I have a question for the list.
Can you use RG-6 coax to feed the loop and still using it on all bands with a tuner. My last loop came crashing down with a few trees in a storm we had. It was feed with ladder line, but where I want to put this loop is too far away for what length of ladder line I have.

Hi Hal,
RG-6 coax will work fine with 100 watts , I would be cautious about QRO operation.
Line loss will be greater than with ladder line.
I am feeding my 272' horizontal loop antenna with coax.

I never run more then 100 watts anyhow.. I thought about using the ladder line that I have and putting a 4:1 voltage balun then running the rg-6 the rest of the way. But that sounds like more work then I really want to do.

1172. want to build some loops

Yahoo group: SkyWires
Date: 2005-06-06 00:26:13 UTC
From: Sarge
Topic: 1172 Message: 1172

I need pointers and info and calulators or formulas and lots and lots of advise.
While I'm not totally unobstructed here, I do have 3 acres immediate to the house to play with.
I'd like to build one first for 6 meter SSB work. Then I'd like to go with an 80meter or 160meter. I want full wave or half wave loops.

any help is most appreciated,

Sarge W5SRG

Hi Sarge ,
For 6 mtr SSB , I would make a Vertically oriented , Horizontally polarized , Diamond shaped , full wave loop. Hang it from the top corner . Use a spreader about 7 ' 3/4 " across , PVC pipe works great.
Feed the bottom corner.

1181. Re: [SkyWires] want to build some loops

Yahoo group: SkyWires
Date: 2005-06-06 05:17:04 UTC
From: Dr.Ace Ratliff
Topic: 1172 Message: 1181
Attachments: 1 described; binary payloads are missing from this source WARC

On the higher frequency bands a full wave loop antenna can be oriented as a vertical diamond or vertical cube. Fed at the top or bottom corner of a diamond this antenna has horizontal polarization.
Let me clearly state this Fact.
"A vertically oriented horizontally polarized one wavelength loop antenna with the bottom of the loop 1/2 wave length above ground is a FINE antenna".

Do NOT put the bottom of the vertically oriented loop more than 1/2 wave length above ground for DX contacts.

If you feed the Full wave Loop antenna direct with a single piece of coax you can only adjust add/prune the antenna till the VSWR gets down to about 1.7:1 at resonance , so you will probably want to use a tuner if you want to cover an entire HF band . And Yes the tuner in the radio will work fine as long as you are not using a linear amplifier. The impedance of a Full Wave Loop antenna is theoretically in the vicinity of 100 ohms. That is why I use a 75 ohm "Q section" to provide a perfect match to the 50 ohm coax. My Loop antenna is flat 1:1 VSWR around 3.875 Mhz and rises to about 2:1 SWR at 3.75 and 4 Mhz . So I cover the entire 75 meter phone band without using a tuner.

Here is How I Do It.

IMPORTANT - Connect the shield of a "Short Piece" of 75 ohm coax to one end of the loop antenna , Connect the center of the 75 ohm coax to the other end of the loop antenna. The length of the 75 ohm coax is most important. It will be used as a Q section.
To determine the length to use, Use this formula "Length in feet = 246 x VF / Freq in Mhz"
VF = the Velocity Factor of the coax. So multiply 246 by the Velocity Factor of the coax , Then divide by the frequency .

If you use RG59 or RG11 with a Velocity Factor of 0.66 , For the 75 meter band the Piece of 75 ohm coax should be about 42 feet long , It doesn't need to be exact . RG59 and RG11 coax usually have a Velocity Factor of 0.66 , Foam dielectric coax such as RG6 might have a Velocity Factor of 0.81 or more.

Put a PL259 coax connector on the unused end of the 75 ohm coax, Screw a PL258 double female coax connector onto this PL259 coax connector. Then connect 50 ohm coax to the other side of the PL258 double female coax connector, Use any length 50 ohm coax needed to reach your Transceiver.

1184. RE: [SkyWires] want to build some loops

Yahoo group: SkyWires
Date: 2005-06-06 04:47:02 UTC
From: D. Scott MacKenzie
Topic: 1172 Message: 1184

It will feed with 50 ohm coax, with an SWR of approximately 1.5. If you want to make it perfect 1:1 - you can trim to the lowest SWR, then make a simple transformer. But most times, I just leave it be.... it works just fine...

OK. How long is the wire? Can I feed direct with coax either 50 or 75 ohm? I don't have a tuner for 6 meters.

Hi Sarge ,
For 6 mtr SSB , I would make a Vertically oriented ,
Horizontally polarized , Diamond shaped , full wave loop. Hang it from the top corner . Use a spreader about 7 ' 3/4 " across , PVC pipe works great.
Feed the bottom corner.

Attachments: 1 described; binary payloads are missing from this source WARC

It has been my experience that I could only trim the antenna until the VSWR dropped to 1.7:1 using all 50 or all 75 ohm coax. I agree it will work just fine.
As far as making a simple transformer that is exactly what I suggested, a coaxial impedance transformer.

Get some more ladder line. You lose to much in feedline loss with coax in a tuner load side setup.

Subject: [SkyWires] Using 75 ohm coax

I have a question for the list.
Can you use RG-6 coax to feed the loop and still using it on all
bands with a tuner. My last loop came crashing down with a few trees
in a storm we had. It was feed with ladder line, but where I want to
put this loop is too far away for what length of ladder line I have.

Hi,

I believe this list started as an off shoot of the 'loop antenna' list. On that list most of the participants were primarily interested in small tuned loops and there were a number that were more interested in large primarily horizontal loops. After some antagonism the group with the large (one wavelength and up) loop interest started this user group.

I follow both groups and the 'loopantenna' list and the 'skywires' list have stayed primarily on those 2 tracks. However, this group is pretty open and I don't think anyone will object to someone posting something concerning long wires or dipoles. After all wire is wire and there are a lot of parallels .... especially concerning the feed systems of dipoles and loops. For example, feeding a loop or a dipole as a vertical element against ground is pretty much the same proposition hi hi.

Hi,

The best DX antenna I ever had was a 20M, 1 wavelength vertical loop (square config), mounted on 30' of TV tubing. Actually I also had a similar reflector element up there as well. I turned the whole thing with an armstrong rotor (pipe wrench). I worked DXCC on 20M with 100W of AM. I had the whole thing in a little house trailer. I always think back to that station with nostalgia (DX100 heathkit transmitter and HQ129 receiver).

I fed that antenna with 300 ohm TV twin lead to a balun (an air core balun made of special air-dux coils). I don't remember using an antenna tuner (this was back in 1958-59).

1192. collinear vert dipole

Yahoo group: SkyWires
Date: 2005-06-06 17:32:32 UTC
From: Mel Vance
Topic: 1172 Message: 1192

Well.....since it seems that this should be OK to ask here, at the risk of getting jumped on,
will ask a question that I have not gotten an answer to else where......

If you do not like me asking it here, flame me direct....no need to tie up the list with that kind
of stuff.....

Am looking to build a kite supported antenna....due to the variable wind directions around here, want to use vert dipoles to prevent the signal being directed in an unfavorable direction.

With the max legal height for the kite before I would need to notify the FAA, should be able
to fit parallel collinear dipoles for the bands 40 and above.

Know that it is not hard to add the phasing sections and additional 1/2 wave elements, but never having played around with building one myself, do have questions as to how it affects the feedpoint....

What does it do to the feedpoint as you add sections? Does it change the R and/or J? Plan to use rg6 (have it to use.....due to wind generated static, do not think bare wire bal feed line
would be a good idea), will I still be able to get an accurate reading of the antenna feedponit
at the end of the coax on a 50ohm antenna analyzer?

Used to know what happens with these beasts, but have forgotten, and the antenna books I have on hand mention collinear dipoles, but do not give any details on them......have not found any useful info on-line......

Howdy all.... I recently put up a horizontal loop and am very satisfied with it. I will ultimately work my way up to a skywire. I am in the process of adding an amp to the equation. I currently feed the loop with RG-59/U, but need to determine if the RG-59 is able to handle 5-600 watts. I know there are tables for this, but can't remember where they are. Anyone out there able to help? Thanks, Paul NN5G

1194. Re: [SkyWires] collinear vert dipole

Yahoo group: SkyWires
Date: 2005-06-07 13:08:19 UTC
From: JimMcSkate@aol.com
Topic: 1172 Message: 1194

My ham club tried a kite supported longwire antenna a number of years ago, and it was kind of a bust because of static noise - field day in these parts can be humid.

But you raise an interesting possibility - use two kites of significant lifting power, space their stakes a few hundred feet apart, and raise a horizontal loop! The loop will be much less prone to the sort of static that affected the kite raised longwire, methinks.

Say you have the kits up 200' with wire going up to both kites and horizontal wire connecting the kites... perhaps use a third kite in the middle of the horizontal element span to support it... then connect the loop at the bottom, as near to the ground as you'd like. Drive that with ladder line and you'll have an interesting experiment to report on.

My sister used to work in a sail loft, and I got the scraps to make kites with when I was a kid. Can't say I ever tried something this ambitious...

I've drawn it on my whiteboard; maybe one of the scientists on the list could comment on the three-kite configuration and speculate on performance??

73,
Jim
WA2LGN

PS: I had no idea there was a schism on this list - I for one am happy to read about antennas, loop or longwire... I learn from everyone and everything, which is why I like this list so much.

I thought of a loop also.....will try that in the future.....was wanting to try the vert first to cut
down on the level of complications at first.....also, was looking to run 2 rigs at the same time....20SSB and 30CW/DATA with a single feedline though a band splitter....

A major problem that you will encounter with a kite supported antenna is static build up on the system....could be what you had with your kite longwire.....a bleed resister is needed.....
it is worst with bare wire, but even insulated wire builds a rather large charge.....melted about 2 feet of wire when it discharged as I was bringing in the kite on my kite supported longwire experiment......

Doing research on kites for lifting, looks like a vented sled is the way to go.....there is one
that I have found that is around $60 and is recommended to be flown with (and my mind goes blank....) 200lbs line or better.....Also, have plans for building one of similar size
yourself.....and sources for the rip-stop fabric and 'bulk' kite line....even some with breaking
strength in the 1200lbs range.....

Anyone interested in discussing kite designs and kite supported antennas, would be glad to do so off list to keep from upsetting anyone for OT stuff.....

Still trying to find out about how adding phasing sections and collinear elements alters the
feedpoint of a dipole.....

You realise of course you also have a kite borne lightning rod. I have been watching the discovery channel and when they want to attract lightning they raise a wire into the air with either a kite or a small model rocket. Most of the time lightning will come out of nowhere and strike the wire. Then they record the niformation with high voltage equipment.

Some of the "Live-Wires" have been experimenting with kite-lifted antennas.
Dave Hatch, N9ZRT (n9zrt@...) has done it several times, but I think he
is mainly looking at the "fun" factor rather than theory.

See http://groups.yahoo.com/group/Live-Wire/ .

I recently put up a horizontal dipole collinear consisting of two 40 meter dipoles seperated with a 30 foot rope and fed (each one) with 45 feet of ladder line that is commoned to 68 feet of RG6. I routinely check into the California Amateur Radio Emergency Services net (Bay area) from near Mt. Rainier (Wa. state) and the signal reports I get are 1 1/2 to 2 S-units better than my hex beam. Collinears do work. 73 jon ad7aw

From: Hal
Topic: 1200 Message: 1200

I'm happy to announce that I got my new loop up today. My first QSO with it was with an Australian Station and I received a 559 report. And that was at midnight my local time on 20 meters. So I would have to say "Yep, It works."
Right now its just fed with RG-6 but I'm going to change it to RG-8 or RG-8x sometime this week.

From: Sarge
Topic: 1200 Message: 1203

Cool! What size is it and whats it made from?

I'm happy to announce that I got my new loop up today. My first QSO
with it was with an Australian Station and I received a 559 report.
And that was at midnight my local time on 20 meters. So I would have
to say "Yep, It works."
Right now its just fed with RG-6 but I'm going to change it to RG-8 or
RG-8x sometime this week.

My loop is made from 14 AWG THNN wire. Its cut for 40 meters as I don't have enough space for an 80 meter one. I have about 15 feet if 450 ohm ladderline then a 4:1 balun. I was using RG-6 but tried some RG-58 that I had today works fine.

I did find one strange thing.. On 40m I can tune up in the lower half of the band but in the Phone sub-band the best I can tune up is a 2 to 1 SWR. The rest of the bands are all 1.7 to 1 or lower.

Hal ,
It sounds like your loop is a little long.

Put the ladderline back on, and use a true balanced line tuner. You'll be amazed at how much better a loop will work by not using coax, or a toroidal balun.

Well I have solved my problem on 40 meters. The way I solved it was by changing the length of the coax for the CW band or the Phone Band. Not the best solution but it works. It might also be my tuner, which is a Z100 autotuner. I never had this problem with my mfj-949e. Which is not working right now as the inductor coil arced one day. But that is a different story.

Hi all,
Lets go back to basics and remember that the impedance of a loop is
about 230 ohms.
The way to match it up is to connect a 1/4 wave length of 75 ohm
coax to the antenna cut for the lowest frequency (in this case 40 M
and remember to calculate the length using the velocity factor of the
particular coax). From the end of the 75 ohm coax connect to 50 0hm
coax of any length to the rig.
Forget open wire lines and things like baluns. Go with the coax
matching section. Using other ideas systems to attempt a match can
produce high voltages at the tuner with flash over possibilities.
ACE has a good reference to a reduced size loop that works well but
you should research the calculations and fully understand how and why
it works.
Those long lengths of wire in a loop can pick up a lot of Static
voltage so
it is a great idea to connect a 2.5 mH Rf choke to ground at the
transceiver. The size of the choke is about 2 inches long and has
several "Pie sections".
This choke will not affect the rig or antenna operation. It can
burn out however if you have a nearby lightning strike so remember
your grounding relays as well.

Much Snipped.

Using coax as a matching section is fine for a monoband loop. You can't run this loop on higher bands, it all depends upon the requirements for the antenna. Using balanced line, and a Z-Match tuner is the best approach to multiband use of a loop. Even on the band it's designed for, you'll notice slightly better performance with the loop. The Z-Match tuner provides a much higher Q than the coax transformer approach. Easily verifiable by noting the bandwidth at resonance. With my 80m loop, b/w on 20m was about 100 KC. This loop was fed with about 40' of 450 ohm ladderline into a homebrew Z-Match. The Z-Match I chose used an air core inductor which handles really odd impedances better than torroidal cores. Don't have to worry about saturation, heating, etc.

I guess what it all boils down to is the loop going to be monoband, or multiband.

Hi all .... Mark,

I couldn't agree more. I have used various sizes of loops as well as dipoles, extended double zep, and straight zeps. The absolute best way to feed them is with open wire line and a Z-match antenna tuner. The system maintains balance and feeds just about all frequencies. The efficiency is much better than the balun/coax/tuner route and unlike the coax matching section approach, facilitates multi-band operation.

Unfortunately the Z-match tuner is not very common these days (commercially) but rather easy to build. There are some really good

articles on the Web .... The model I am using is a 100W model (commercial) manufactured in the UK (years ago) ... the KWezee match .... tunes all bands with no band switching !!! The Web articles show the construction of a more robust model. By the way, I have never had a flash in the my more modest tuner .... I usually run about 20-50W output .... however I have gone up to over 100W , but not that often .... I'm not afraid of the power, just the neighbors (considerate) hi hi.

Here's the Z-Match tuner I built for about $60USD. Most of the variable caps I got from the swapmeet, and I purchased the dual ganged one from Oceanstate Electronics. It's pretty easy to build, took about 5 hours from start to finish. Here's the URL:
http://www4.tpgi.com.au/users/ldbutler/SingleCoilVK5BRCct.htm

1214. question on coax...

Yahoo group: SkyWires
Date: 2005-06-18 01:27:55 UTC
From: Mel Vance
Topic: 1214 Message: 1214

OK...I know that most here favor open line or ladder line.....need to ask about coax for my
kite supported antenna experiment.....

Going througn the feed line I have on hand, have nothing that will be long enough, so will need to patch together several chunks.....have some with BNC's on them....what would it do if I used a T connector to join 2 runs together....IE....use to 'ports' and left the 3rd open......

Will this cause a problem?

Have a bunch of old computer networking RG-58 on hand and several of the T adapters on hand....

Before I spend lots of money I do not have on new feed line, want to make sure I have a kite that will handle the load.....

Mel -- I'm not a negative guy, and I like a challenge, and even more, I like helping others solve problems. I mean this to be a thoughtful, serious message, and do not mean to be pessimistic common negative, or sarcastic in any way.

Yet, I'm having a real hard time imagining how you are going to accomplish this feat. I'm thinking about the weight of the wire, its length and mass. I am thinking about the size of the kite, and how big it must be to handle the wavelengths you want to work with, and carry sufficient wire to do that. I'm thinking about how the wind changes, so frequently and so dramatically. I'm thinking about how you are going to control the kites while in flight, and operate your radio at the same time. I'm wondering where you will find the room to do this without getting tangled up in the rest of civilization and its artifacts. I'm wondering how long you're going to be able to keep the kites up, in a stable configuration and position. I'm wondering what you will do when the wind shifts dramatically, as it does in my location, without warning, and with great frequency. And I am wondering how you will gather it all back in at the end of the day?

This kite things sounds kind of fantastic. Am I way off base? Could you take a moment to explain how this will all work, and how you're going to manage it? It is a fascinating comment interesting and intriguing notion, but I just can't fathom how you're going to pull it off!

Happy trails to you. (I will understand if you just ignore this post and continue with your project... but I am serious in my inquiry and do wish you all the best in this endeavor.)

Best Regards. ///// Richards //////

Hi,

I have used a T connector to splice coax line many times and have never
noticed any difference from a straight through type connector. I have a
lot of T connectors in my junk box hi hi.

Sorry to butt in fellas. I remember years ago a project that was an off shoot of a military emergency antenna system using a box kite. The box kite is fairly stable and supposedly will work. Don't know for how long but it should allow you to raise a 14 gauge lanyard. I do think that you may not want to do this if you your weather is changing. Might end up duplicating Ben Franklin's lightning experiment.
my 2 cents.

Kinda done the Ben Franklin thing....was testing a kite supported longwire...almost an end fed inverted V in shape...still a random longwire...after disconnecting everything to retrieve
the kite, enough wind generated static built up that, when the end touched the ground, 2 feet
of the wire vaporized......

Lesson I learned...keep the static discharge resistor in place until the whole thing is down......

> sarcastic in any way.

Not at all...I am still figuring things out and revising my ideas.....already have run into things
I need to re-think.....And, I seem to be coming to the conclusion that there is no 1 answer....looks like I will need different kites for different wind speeds....

You may be picturing a smaller kite than I am trying to use....this is a fair sized kite....designed for 'lifting'...recommended by more than one kite shop....they use them mostly for lifting teddy bears and dropping them on parachutes.....based on what I saw today, it may still be too small for the 5-15MPH wind at the time...part of why I intend to do
side by side comparrisons on test kites to find something with more lift......

The area I intend to fly is Ft. Casey...a former costal defense installation....1000's of feet of
clear flying area....winds tend to be fairly constant out of the South (longwires tend to be
directive North leaving very few contact opportunities...why I am looking at a vert dipole) and do vary in strength. The kite designs I am looking at do not require a huge amount of playing to keep them up....also, will be anchored to the rear bumped of my van where the rig will be operated from, so will be able to look at the kite from time to time.....

Am also referring to some web sites I found searching for kite supported antennas...there are a few sites out there, so I am really just re-inventing what others have done..only thing I
think I am trying different is a vert dipole...others seem to be sticking to lots of radials and a
1/4 wave vert or longwires....I am trying to avoid having to use a bunch of radials as this is a
popular park and do not want trip hazards.

May also try a delta loop and see how that does...would need more line anchor points and may not work in the park.....

If any one is interested in more discussion on kite supported antennas, we may want to move it off the list....some others may not be interested.....

Hope I hit all the points you brought up....

1220. Kite testing

Yahoo group: SkyWires
Date: 2005-06-18 15:17:56 UTC
From: Mel Vance
Topic: 1220 Message: 1220

Will be attempting to get a kite supported antenna in the air today....

For those that are interested, will be starting to get the kite up starting around 11AM West
coast (1800Z if my math is correct)...IF I can get a vert dipole up, look for me on 28.4 or around 14.250 sometime after that for on the air testing.....Will attempt the 10mtr antenna first as it will have the most wire in the air. If it works, will try a few contacts before attempting to get the 20mtr version up.....

Due to limited power (will be on battery only...no recharge ability), will not be active on the
air for huge amounts of time...As RX uses less power, you may try calling me....may be up and listening....expect the soonest I could be on the air would be around noon (1900Z).....may be on 20 by around 12:30-1PM (1930-2000Z)..should be flying for at least 4 hours.....

From: Mel Vance
Topic: 1223 Message: 1223

Well.....over 3 hours of trying and could not even get a kite in the air let alone run an antenna up.......

When you do not need it, there is more than 20MPH wind....when you do...nothing....

Will see if any wind develops in the next few days........

Now....start cutting up garbage bags and make some test kites to see if I can find something
better than what I have......

I don't believe anyone has mentioned NASA World Wind (Google it) for displaying USGS topo maps (and other satellite imaging). You need a fast computer and a broadband network connection to run it effectively.

A similar program, Google Earth, has turned on downloads again (earth.google.com), but this application doesn't appear to do topo maps.

Both are free.

You can order maps from USGS. http://www.usgs.gov/pubprod/

There is also a very good program from a company called Maptech that you can buy that has maps on CDs. It is useful to plot elevation differences and to calculate line of site points. http://www.maptech.com/

Hope this helps..

Hi,

I have a 3" thick window frame made of aluminum with foam sandwiched in between the two sides. I have a 20M dipole (bent) out on the balcony which I feed with 300ohm twinlead to my antenna tuner (it also works on 15M). I use a Kenwood TS-50 transceiver up to full power .... but mostly about 25W on PSK. It works great.

When I started out I simply brought the 300 ohm line through the doorway to the tuner which is located just on the other side of the window frame. This was an inconvenient arrangement and I faced the same question you pose; how can I bring the balanced line through the window frame? I also have a small receiving loop on the balcony which I use for SWL, which is also fed with 300 ohm balanced line to the antenna tuner.

I drilled a small hole, approximately 3/8", through the frame. I then pulled a short length of 110V rubber covered, 2 wire (#16) power cord (I call it zip cord), through the frame. I have about 1 ft on the inside that goes directly to my balanced antenna tuner. On the outside I have about 6" terminated in a 2 pole power connector (female). On the end of the 300 ohm twinlead installed a 2 pole power connector (male). I plug the 300 ohm line directly into the 1.5 ft zip cord which in turn is connected to my tuner. I can easily unplug the dipole and plug in my receiving loop (I just have to remember which one is connected hi hi).

PS ... If I want to undo the operation I found simple pressure fit metal caps that press fit into the holes.

I have not done any rigorous testing, but I have noticed no difference in performance between a direct connection of 300 ohm line to the tuner and one with a 1.5 ft piece of zip cord. If my tuner was a greater distance from the window I would re-attach 300 ohm line on the inside for the run to the tuner. In my case it is unnecessary since the tuner is right at the window.

I have 2 locations .... the one I just described was my city apartment on the 9th flr in Toronto. My other location is a house in a small city (Thunder Bay) where I have several antennas. One of them is balanced line (the rest are coax). The balanced line comes down to a basement window (wood frame). I used the same system here, running a short length of #16 zip cord through the frame. In this case I continue the balanced line on

the inside to my antenna tuner .... about 12 ft. Again it operates flawlessly .... and I operate at the 100W level maximum.

If you want to use heavier insulated balanced cable you could look for the stuff the telephone people use to run from the pole to the house. I find it a stiffer cable and more difficult to use. In any case your only looking at 1 to 2 ft.

By the way before I came up with this simple interim solution I was also looking for some kind of ceramic tubes etc for running through the window frame. But this simple method worked so well I never changed it.

John:
I used to use a piece of 1" x 2" trim pine cut to snugly fit in the window frame while the window is opened. It rested on the sill and had 2 threaded rods going through it with washers and thumb nuts (wing nuts) on each end, spaced properly. I'd close the window on it and place another board vertically from the top of the bottom sash to the top of the top sash for security ... otherwise you can't lock the window.

Topic: 1235 Message: 1240

Hmmmm--- Many times, you will void the window warranties if you drill through the window frame or still.

Instead.....
I like the idea of bringing it through a window, but in a different way and with no destructive alteration:

Simply open the window, and feed the flat latter line under the window. Purchase some rubber foam or other rubber material to use as a gasket, and lay it on the windowsill under the window, and over the ladder line. Just close the window on it all. If you get a thin enough foam or rubber material, but not too thin, you can still close and lock the window as usual, but still be able to accommodate the added insulation and ladder line between the sash and window. That is the real beauty of latter line; it is flat and easily fits under a window without creating a draft. The foam will insure against any draft - probably be better sealed than before!

Just my take. ////////////// Richards ///////////////

Bob--- I say "Nuts! You are working too hard this time!"

(said in good humor, of course...)

I just lay the ladder line down flat under the window and on the sash.
A little foam
laid over the sash from end to end (over the ladder line and all across
the sash) seals it
without messing up the lock thing - just do not get too much foam and
just smash the window down to seal. A little Elmer's glue can hold it
in place if necessary, although my good friend just uses a staple gun to
nail the sucker in place... (making me shudder about the window
warranties, again...)

Just my take. /////////////// Richards /////////////////

Bill,

I'm pretty sure I have one of these! IIRC, it doesn't work very well. I've only plugged it in once, and have not touched it since. It's an IG-102, and goes to 220 Mhz. If you'd like a photo of it, I could send one out your way over the weekend. I might even have the manual, but all that stuff is packed up right now. I'm in the middle of a remodel, so most of my ham stuff is in boxes.

Let me know.

Subject: [SkyWires] Heathkit RF Sig Gen

All
Does anyone have or know of a source to obtain a Heathkit RF Sig Generator?
I think it was ranged from100Khz to about 100 Mhz. I don't remember the model maybe RF 102 or something like that. I am pretty sure it is a tube type.
I sure would like to get one of these generators.

Mark
Thanks for the comeback. I am interested in finding one of these sig gens for my own use. I am not a Heath collector. So I am not willing to pay collectors prices. I have seen what some guys want on some of the ham boards. So before we go any farther, what value are you placing on this sig gen? Whether it works is not an issue, just complete. I have been a tech for most of my life, so fixing things so they work is not a problem.

Bill,

I'm pretty sure I have one of these! IIRC, it doesn't work very well. I've only plugged it in once, and have not touched it since. It's an IG-102, and goes to 220 Mhz. If you'd like a photo of it, I could send one out your way over the weekend. I might even have the manual, but all that stuff is packed up right now. I'm in the middle of a remodel, so most of my ham stuff is in boxes.

Let me know.

From: charles allison
Topic: 1235 Message: 1244

Hi,

I've not done it since I have no ladder line coming in at present, but I was thinking that the so-239 bulkhead connectors might work, if spaced at a decent spacing. I've found them in 4" to 12" lengths. Just run one leg of the ladder line to a separate connector center. I was planning on making up a 2x4 with the bulkhead connectors mounted through it to fit across the bottom of the window so as to keep the airconditioning in and the heat out. However, at the moment, I've got almost as many unused coax cables coming thru the wall as I have in use so I've not done the window mount bulkheads yet. Spacing for the bulkheads would seem at first thought to be about the same as the spacing for open air ladder line of the same impedance assuming the outer shells are floating. I guess it's even possible that the spacing and grounding conditions of the shells may not be relevent.

best regards,

Charles

Haha, you are right. But then, I love to build stuff ... sometimes it works...
Actually, it's an old trick that hams invented long before me and it was usually for coax, but occasionally ribbon or ladder line. If you have several coax cables to get to the other side of the window, the faux sash is a pretty good solution....and it doesn't damage or change the actual window. But you are right, for just one ribbon cable, running it under the sash is far simpler...that's how my outdoor thermometer is wired.

Well, I would, but at the moment it's under the back of the air conditioner, keeping it level.
Just cut a suitable board the full width of the opening...nice and tight fit, and then do your thing with feed thru's...In the fall I'll photograph it....lol.

Okay, JR, thanks for the advice. I was wondering why it was so hot in here....been miserable for the past 2 1/2 weeks....yuck.
Anyhow, I put a diagram of an "Antenna Feed-thru Panel" on my Web site, pretty much the way my old ones were built. Just go to the site and click the "pink link" (hummm) and the "pink link" will take you to the drawing.

Small thought - with the double hung window and the 1x4 spacer, the upper sash of the lower window does not properly seal against the sash of the upper window because the window is not fully closed. This provides access by small insects and, of course, heat.

You will need to put some foam or other material to block that opening.

Sorry I neglected to mention that. I use the kits that come with air conditioners. They have foam strips that can be pushed between the sashes to stop any air flow, hot or cold, and of course bugs.

Hi All,
I have been following the discussion.
Here's an alternate method I have used in the past to run coax thru a double sash window. It works great if you are only using one coax up to a few coaxes.
Start with the window(s) closed. For each RG-8 type coax drill a vertical 1/2 inch hole thru the seam where the upper and lower sashes meet (to the distant left or right of the center window lock). Don't go all the way to the left or right side of the window. The drill bit should be in front of the glass when you start drilling.

Half of the hole will be drilled thru the bottom of the top sash. And the other half of the hole will be drilled thru the top of the bottom sash.

Now with the window open, from outside the house, push the end of the coax up thru the vertical hole (the PL-259 will fit thru also as long as the window is open). After you get enough of the coax in the house to meet your need, close the window. It will form a seal around the coax, and since the coax runs up thru the hole no water can drip in.

If the hole(s) is temporarily not in use, you can put a cork stopper in it (corks are available at hardware stores). If you decide to repair the hole(s) because you are moving, selling, renting the house etc. Wood putty should be an easy fix. Plus the empty vertical holes are much more difficult to notice than horizontal holes.

Just my 2 cents. Ace - WH2T

Neat idea Dr. Ace -- Yet, I offer the following gloss thereon....

1) Can you use a 1/4 inch hole and get a tighter fit on the
coax - 1/5 seems wider than necessary.

2) Great idea -really - unless it voids the window warranty....

3) XYL may not like the cables to run up to the middle of the
window and than back down -- your mileage on this might
vary considering what your XYL considers important.

4) This procedure makes it more difficult to open the window
when XYL says we are going al fresco, and disses the air
conditioner. The sash item can stay put while the window
is opened.

5) Simple - yet genius - that you mentioned it running up -
even if it drops from the roof line - concerning the NO DRIP
aspect. That part of the description bears remembering
in any case !!

Thanks. //// Richards /////

Hi again everyone,
I said drill a half inch hole because I know it has worked very well for me.
RG-8 type coax is about .405" diameter.
7/16" = 0.4375 inches and might work even better , But I am not sure the PL-259 will fit between the glass and the wood with the window open. You could start with a small hole and enlarge it as necessary.
RG-58 type coax is about 0.2" or 5 mm diameter.
The outer diameter of RG-8X is typically about 0.24".
Also, I didn't have any trouble opening or closing the window as long as there was adequate slack in the coax.
As for the XYL , if the coax is installed near the side of the window and you have draperies/curtains they can be adjusted to hide the coax.

OK JEFF..WELL,IT SHOULD WERK FB ON 6..MY DIPOLE WITH
OPEN WIRE WERKS LIKE A BOMB ON 6.HEARS VERY WELL,AND
DX IS GREAT. I REGULARLY WERK GUYS IN NY
STATE,OHIO,MICH.,PENN. ON GROUND WAVE,FROM MY QTH IN
TORONTO,100 WATTS FT847...TIM...SK..

1268. 17 / 6 Meter Loop

Yahoo group: SkyWires
Date: 2005-07-30 01:52:05 UTC
From: n4onl
Topic: 1268 Message: 1268

Hi everyone.
I've been on the air recently with a Cobra Ultralight antenna since i can't put up a low frequency loop. But I've grown an unexpected fondness for 17 meters, would like to give 6 meters a try, and think I can fairly easily put up a center supported 17 meter skywire loop out of the top of my tree to play with. It would be about 40' high.

Now heres the idea, according to the ARRL antenna book a 40 meter skywire loop has gain (over a dipole) and retains a decently omni pattern on 15 meters (3rd harmonic 0f 40m / 3 wave size loop). It just so happens that 17 meters 3rd harmonic hits 6 meters right near the SSB section at the bottom of the band. So theoritically I could scale it down and maintain the same pattern and gain on 6 meters with a 17m loop.

I already heve plenty of BuryFlex (9913 type) coax for the 6 meter KU4AB 6 meter loop (http://ku4ab.com/_wsn/page2.html) I was until today planning on putting up for 6m. Since I'd only be using the 17m loop at or near reasonate freqs/for these 2 bands, I am thinking about coax feeding it with that coax. The tuner in my 746 (classic/non pro) SHOULD take care of any mismatch, which I'm thinking should be small. I have a Daiwa CNW-419 tuner that can be used if needed, its inline now just being used as a wattmeter.

Can anyone forsee problems with this concept?

Any input/comments appreciated.

73
mike

(FYI I scrapped the slinky loop idea before building one, figured it would be too problematic after more research. Currently using a Cobra Ultralite Jr. (http://www.k1jek.com/) 73' linear loaded dipole for 160-6 meters fed through a SGC 237 auto coupler, abt 20' ladder line connecting them, low/sloping. Hey, it got me on the air! And seems to be doing a decent job considering my limitations/restrictions on antennas.)

Hmmm..I would be more inclined to but a loop as large as possible,be it for 20,17 whatever,and feed it with open wire line. this way you will be able to tune all bands,say from 20-6. the tuner in your rig will only make the finals happy,and you wont see the benefits of a loop when it comes to the increased receive.if you can,get a tuner that accepts open wire line,and use that. this is the best way to go. dont be afraid of open wire line,it has no line loss,and after 30 yrs of building antennas,i have only one antenna with coax,and that is a vertical for 160. let us know how you make out. tim...sk..

From: n4onl
Topic: 1268 Message: 1270

Hi Tim, Thanks for the reply.

17 meters is about as large as is practicle as I judge it, and is the band I'm most interested in. Also 10' spreaders will make them easier to find locally. 20 would need about 13' spreaders.

I don't want to tune all the bands from 20-6 with a loop. A loop for 17 and 6m would make me happy, especially if I gain some performance (and omni pattern on 17m) over the other antennas on those bands. Heck last go around being active on HF I was stuck on 10 meters only, I now have orders of magnitude more frequencies to use with the Cobra antenna (160-6 meters).

I bought the SGC for that antenna to bring coax into the shack, and have autotuning. I dont want to use a manual tuner. I don't have to. I dont want to buy another 327 right now. I'm currently putting my dollars into getting a HF mobile setup for the truck. I have a 706, a used screwdriver antenna on the way, and looking at auto controllers for it (turbo tuner?).

All any tuner does is make the finals happy and keep the power out up (SWR protection from curtting in). A friend calls tuners/couplers foolers, and I agree. Resonant single band antennas will preform better, in my meager experience. Going from 1.8 to 54 mhz on one antenna is a comprimise. The Cobra antenna is my comprimise.

The proposed loop for 17 and 6 meters would be resonant on those bands, not needing open wire feedline and wide range tuner to keep the finals happy, wouldn't ir? Just some SWR tweaking, possibly. A loop for 18.13 mhs has its third harmonic on 54.39 mhz, just above the 6 meter SSB section of the band, which is what I'm after. IMHO SSB Rulez! (160 to 2m SSB is my goal) B)

I'm not afraid of open wire line, I choose to use it only where needed, and in this case since I dont want to tune 1.8-54 mhz continously with one antenna I don't see the need for it. If there is a need for it with a 17m loop, as proposed, please enlighten me.

As I see it the little line loss at these frequencies wouldn't make much difference between coax and open wire, if any, in signal at the other end. As long as they hear me, mission acomplished.

Its not that I have fear of ladder line, its that I have nothing against good coax, when ran at reasonable SWR levels. At reasonable swr levels on the feedline, how does open wire beat coax?

The Cobra antenna, is basically a 40 meter antenna by size, but I use it on 160 and 75 also, with deminished efficency, with ladder line to the coupler, and unbalanced coax to my unbalanced rig. But it does what I intend it to do, talk to local friends on 75 and 160.

A place for everything and everything in its place.

I may start rounding up parts this weekend. It will be a while before I can get anything up in the tree, I have to get everything ready for 3 antennas going up in it, (dual band vert, 144 horiz omni, and something for 6m) and round up a tree climber to put them up there for me. The tentative date is before winter. The nount is done, the pole is ready, as are the 440/144 antennas. 6 meter antenna in the tree is up in the air,and getting a loop up for 17m would be a bonus! B)

Thanks Tim,
I picked up some FG fishing poles yesterday, and ordered some antenna wire and 75 ohm coax (Q section). I will give it a try and post results, but it may take a bit of time. The screwdriver ant. for mobile is on the back burner for now (it should be here tomorrow). I need to design and make a mount for the poles, probably with the help of KB4WXD (Machinist and welder, and partner in crime! ;))

(more about ladder line vs. coax below...)

> > As I see it the little line loss at these frequencies wouldn't make
> > much difference between coax and open wire, if any, in signal at the
> > other end. As long as they hear me, mission acomplished.

(to all in genreal...)

Ladder line vs. coax
("little line loss", I may have miss spoke)

"Ladder line performance degrades significantly when wet, and a better type of balanced line should be considered in environments that are commonly subject to rain, fog, frost, snow, ice etc. Using XLZIZL to explore the impact of wet ladder line, at 3.6MHz the loss on the 9.85m of Wireman 554 would increase from 1.7dB dry to 9dB wet."
http://www.vk1od.net/G5RV/

Figure 8. ... ("Fig 8: Wet Wireman 554 ladder line - 15.15m RG58C/U - tuner") http://www.vk1od.net/G5RV/LossRG58w.gif

OTOH Buryflex (http://www.davisrf.com/ham1/coax.htm#buryflex) is rated for 1.1 db loss at 50mhz/100 ft. compared to ladder lines dry loss of 1.7 db loss per 9.85m @ 3.6 mhz. (as stated above), roughly 32 ft., approx. 4x the loss of buryflex at the same length and Buryflex at 50mhz, not 3.6 mhz. 100' of wet ladder line at 3.6 mhz would be approx 14 db loss. Whew! Talk about turning QRO into QRP!

According to fig. 8 (above) at, 18 mhz wet ladder line would have approx. 7 db loss/32', compared to Buryflex's 0.52 db loss for 3 times the length at 10 mhz. (probably about 0.3 db loss at 3.6 mhz. for Buryflex), Of course wet buryflex's losses might go up a bit, but I seriously doubt, IF it does it would come close to 14 db./100'.

IOW, if the above data is accurate, ladder line is not always your friend.. I don't know about where you live, but here its often wet (rain, fog, frost, snow, ice etc.) here during the fall and winter months, when I'm more apt to stay inside and operate.

Food for thought.
(or discussion)

73
mike.

1276. Should I use the extra length

Yahoo group: SkyWires
Date: 2005-08-04 01:12:45 UTC
From: Paul
Topic: 1276 Message: 1276

Articles I've read show the total length of a skyware (horizontal loop) to be about 270 feet for 80M and 143 feet for 40M. I'd only be interested in 40M and up, but my masts - doing double duty, would give a total of about 200 feet around.

I can make the loop that big - bigger than needed for 40M, less than needed for 80M - or, by lengthening the support line for the skywire, I can rig an exact 143 foot square "inside" the area bounded by the four masts.

Will the extra 70 feet just give my tuners more work to do - so keeping to 143 feet is best, or aside from the additional wire cost, is there no down side to giving the loop an extra 70 feet.

Thanks and 73,
Paul

...COMERCIAL LADDER LINE (read cheap)does have loss when wet,rain,snow fog.etc..but homebrew ladder line doesnt have these figures.homebrew ladder line is usually made from 12-14 ga wire,even #10. your typical ladder line is maybe 16ga. as well,it is also known as window line,because it has retangular holes punched out,to reduce the wind load and general weight. and,it is generally junk. do yourself a favour,buy the 12ga wire,make some spreaders,and put it together...if you space it 4-6" apart,your antenna and rig will love you..p.s.,the reason ladder line is prone to loss,etc is that the "windows" are'nt wide enough,and water,etc bridges the feeders...tim...sk..

Hi Tim

I am using a current indicator in my open wire feeder. The description in on this page
http://www.tematra.se/files/atu.pdf
from a radcom newspaper.
The page itself is in swedish but the article is in english so let me know if You need some help.

If you are using open wire feeders then you can use a small
flashlight bulb with 6 to 8 inch leads attached. Tap the leads along
ONE SIDE of the open wire feeder. Don't cut the feeder, just connect
the leads 12 to 15 inches apart on the one side only. The bulb now
measures voltage developed across the current flowing in that section
of the open wire.
Again, the leads just clip and bridge over a length on to one leg only
and not across the two lines. Don't cut the leg . make sure the
insulation is removed or the copper is clean.

greetings
I just came back from that website, pointed out below.. I love that circuit...
I can use plastic water pipe for the coils... but I have a question.. probably more later, how to do wrap the coil so nicely, which just neetly spaced coil turns....??

Use string or rope the appropriate diameter as a
spacer between the copper or aluminum wire turns.
After you have the wire wound and tied down at both
ends simply remove the string or rope spacer material.
I wrote a detailed article on antenna tuner use and
operation and included information on how to make and
use light bulbs amp meters to check for a balanced
condition on the feed line and a relative loss check
through the tuner. The article link is
http://www.eham.net/articles/9751

SCOTT...THAT IS A GREAT ARTICLE,I'VE REFERRED TO IT NUMEROUS TIMES...AS IN THE PREVIOUS POST REGARDING THE METERS,I WILL MAKE THIS METER ASSY,AS I WANT A DEDICATED SYSTEM. ALL MY TUNERS ARE HOME BREW,AND THEY ALL INCORPORATE LINK COUPLING. I FIND THIS IS THE BEST SYSTEM,AND IN YOUR ARTICLE THE PIX OF THE JOHNSON MATCHBOX HAS JUST THAT.AS MANY KNOW,THE JOHNSON MATCHBOX IS STILL THE ONE THAT IS REFERRED TO,AFTER ALL THESE YEARS. LINK COUPLING IS IN MY OPINION THE BEST,AS MODERN TUNERS THAT USE BALUNS MAY INDICATE/TUNE FOR MIN.SWR,BUT MORE TIMES THAN NOT,THE SYSTEM IS NOT BALANCED..BUILD YOUR OWN TUNER AND OPEN WIRE LINE,AND SEE THE DIFFERENCE!
...TIM...SK..

1284. 80 meter Loop Question

Yahoo group: SkyWires
Date: 2005-08-07 17:43:24 UTC
From: Bryan
Topic: 1284 Message: 1284

Greetings,

I have been away from posting for sometime. I do copy the mail here periodicly.

I have been working on an 80 meter loop design. my 160meter loop came down when a 50ft tree fell in my yard. Thank God it didnt take out the house.

I have posted a PAINT document in the FILE section with my call sign as part of the file name.. If you all could look at it and comment I would appreciate it.

Im mainly asking if this antenna would be efficent in this layout. just by way of more information the ladder line in the picture is about 35-40ft long and coax is about 20ft of 9913. the loop itself is 278ft total length.

all comments welcome..

1285. Wire Gauge for QRO

Yahoo group: SkyWires
Date: 2005-08-07 17:44:41 UTC
From: professormobesser
Topic: 1285 Message: 1285

What thoughts do folks have about the appropriate wire gauge to use for a loop skywire when running 600 watts of peak RF output power?

I'd like to put up a stealthy system made from #22 stranded, black-plastic-insulated copper wire. Such wire comes in nice, inexpensive 90 foot rolls from Radio Shack for about 5 bucks each. With three of those rolls, I could have a 270 foot loop; about a full wavelength on 75 meters. And it would sure be stealthy.

But would #22 copper wire get too hot when conducting 600 watts of RF?

As I recall, RF mainly flows on the surface of the conductor. Of course, the surface area of #22 would be smaller than the surface area of #14. But pure copper should have better conductivity than the typical #14 stranded bare copperweld, especially after the surface of the copperweld has been exposed to the elements for a few days.

Any thoughts, theories or empirical data on this?

1286. Re: [SkyWires] Wire Gauge for QRO

Topic: 1285 Message: 1286

Also keep in mind that the smaller the wire the smaller the bandwidth. Also is this a permanent installation?

1288. Re: Wire Gauge for QRO

Yahoo group: SkyWires
Date: 2005-08-07 20:23:00 UTC
From: professormobesser
Topic: 1285 Message: 1288

I'm not too worried about bandwidth. My amp is an Ameritron AL-811 which can easily handle 3:1 SWR. And when running barefoot, the rig has an internal tuner.

I'd call the installation semi-permanent. The main thing I'm concerned about is the power-handling capability of 22 gauge copper wire.

1290. 300FT LOOP..TUNER FOR 6 METRES?

Yahoo group: SkyWires
Date: 2005-08-08 21:49:09 UTC
From: ve6pg
Topic: 1290 Message: 1290

..ANYBODY HAVE ANY IDEAS FOR A TUNER FOR BALANCED LINE FROM A 300FT HORIZONTAL LOOP,FOR 6 METRES?.THIS CAN BE A DEDICATED TUNER FOR 6,NOT NECESSARY TO HAVE BAND SWITCHING...TNX..TIM...SK..

1291. Re: Digest Number 394 stealth wire

Yahoo group: SkyWires

From: professormobesser
Topic: 1289 Message: 1291

Thanks for the suggestion. Being copper-clad stranded steel, this stuff would be stronger than #22 stranded copper, and more resistant to stretching.

As far as the power handling capability is concerned, I wrote to LB Cebik, and he says the #22 plastic insulted copper, being air cooled, should probably be fine for 600 watts PEP SSB, or 500 watts CW. AM or RTTY might be a different story, however.

1292. cleaning aluminum

Yahoo group: SkyWires
Date: 2005-08-11 13:49:27 UTC
From: johntr@myway.com
Topic: 1292 Message: 1292

What is the best way to clean aluminum antenna elements?
this old vertical I picked up is encrusted with what looks like dried salt spray . Most of it chips right off.
Thanks

From: Scott Erwin
Topic: 1292 Message: 1294

That?s aluminum oxide. You will need to clean all that off, as it will affect the performance of the antenna. RF flows on the surface of the aluminum and the oxide will cause problems. You might consider joining the yahoo group Butternut-antennas at http://groups.yahoo.com/group/Butternut-antennas/ . Even if it's not a Butternut vertical you will find lots of information and help about vertical antennas in general. One file available goes into detail about refurbishing Butternut HF vertical antennas including cleaning and polishing aluminum tubing. You can follow a link from the group site that makes Butternut antenna manuals available for a free download and these antenna manuals for the HF verticals go into great detail on installing ground systems under HF verticals appropriate for any model of HF vertical antenna.

Yes they will. When you're using very large loops on much higher frequencies, they tend to act more like rhombics than simple loops. Many good reads can be found here: http://www.cebik.com/radio.html <http://www.cebik.com/radio.html>

73 & have a blast with loops!

Lee,

If you will go to www.lwca.org and look up Bill Ashlock in the part 15 LowFER's he has tons of information available on loop antennas for 1750 meters. His ID is WM and he is on 185.30 kHz.
Several stations run them now , however Bill is the master of the design.
...Charlie...KC0EH...COV...185.297kHz.

HI all,

I'm curious, what is the difference between feeding a loop at the corner VS feeding in the middle of a side.

any idea what to expect for impedance on the feed.

thanks Bryan

1303. Re: [SkyWires] question about loop

Yahoo group: SkyWires

From: tim smith
Topic: 1302 Message: 1303

bryan...it depends on how the loop is mounted. if it
is horizontal to the ground,it makes no difference.if
the loop is "standing on it's end",fed at the bottom
it will give it horizontal properties.fed at the
side,it will have vertical properties.a loop fed at
the corner,will have sort of a polarization that is
angular to the horizon. some guys do this,and tell me
they get vertical antenna take-off properties,with
less man made noise,which is vertically
polarized...tim...sk..

This is all true, until your rf hits the ionosphere, then no one knows the polarization after reflection....

...good point mark..i guess it really amounts to what
a guy wants,horizontal to reduce noise,or as
mine,horizontal to the ground,and basically a
cloud-burner nvis..a friend of mine has his vertically
polarized,strickly to reduce the splatter from a local
ham,who has horizontal dipoles..works well for
him..sk..

1307. rf amp meter thermocouple

Yahoo group: SkyWires
Date: 2005-08-18 13:12:06 UTC
From: leekwon1
Topic: 1307 Message: 1307

Hi yall looking for any information on building or making rf amp meter therocouples, there are 4 or 5 boxes of meters here and i would like to use them for cheap watt meters. Lee

1308. skywire of sorts

Yahoo group: SkyWires
Date: 2005-08-21 19:26:28 UTC
From: hgxrp
Topic: 1308 Message: 1308

Due to a small and irregular lot, I've been confined to using in-roof antennas. My primary antenna has been a 33 foot folded dipole w/stub (see message 2471 of the RX320 group) connected via a tv 300/75 ohm balun to coax.

The dipole is broadband enough to give me coverage over most of the HF spectrum, but it is most senitive at its resonant frequency (14 mhz) and is basically directional.

Since I like to listen to LW and do some BC band DX, I also use a long wire (directly connected) thrown out of a second story window and run around the perimeter of the property on a partial fence. It is subject to noise and is in need of replacement.

My thought has been to erect a skywire (in-roof)about 30 feet on a side (120 feet around). I'm of the opinion that I would need more wire to cover all of the HF freqs as well as BC and below.

I came up with a plan to use multi-conductor wire (telephone or similar) and a switching network which would add 1 wire (additional 120 feet) at a time, to the loop. The wires in the roof would all be in phase. The wires connecting the loop (roof) to the shack (2nd story) where the switching network would be located, are bi-phasic. I could shield the two phases from each other.

The end result, I would hope, would be an antenna which could be 'tuned' by adding/subtracting length and would be omni-directional, thus overcoming the minuses of my dipole.

I'm asking the resident experts to tear my idea apart. Would it work? What total length is enough? Would it be necessary to use remote switching in the roof? Would a balun connecting the switching network to the receiver (via coax) help?

Thanks for your input.

Harold

1311. SkyWire Loop Antenna [Was: Wire loop.] Question

Yahoo group: SkyWires
Date: 2005-09-21 09:11:11 UTC
From: R H F
Topic: 1311 Message: 1311

Terry,

SkyWire Loop Antenna [Was: Wire loop.] Question

If both ends are coming together to form a Loop :
Then it is Balanced and can be feed directly via
Ladder Line or Coax Cable. With Coax Cable as a
Feed-Line; you could also use a 1:1 Matching
Transformer (Balun) if the Loop is going to be
used for both Tx & Rx.

NOTE - 240 Feet of wire puts you at about 4.2 MHz
with a SkyWire Loop Antenna.

FWIW - If this Loop Antenna is 'only' for Receiving
then a 4:1 Matching Transformer (Balun) could be use
with Coax Cable as a Feed-in-Line.

SKYWIRE LOOP ANTENNA :
This type of Large and Low Loop Antenna is generally
called a SkyWire Loop Antenna. There is a specific
group for builders and users of SkyWire Loop Antennas
on YAHOO ! => http://groups.yahoo.com/group/SkyWires/

This group is for people interested in building and
using a Sky-Wire Loop Antenna
SKYWIRE => http://groups.yahoo.com/group/SkyWires/

This group is for the Radio Experimenter who wants
to Learn and Exchange their Knowledge and 'secrets'
about the SkyWire Loop Antenna.

Looks to me like a cone pointed up, on top of a second cone pointed down. With a lot of insulated guy wires from the middle going outward, to hold it open.

Vaguely similar to the old AM broadcasting towers that were narrow on top and bottom but bulged out in the middle, only much more extreme. I think it makes them more broadband.

Andy

They were reather interesting design to me as its
the first time I had witnessed this type, I have seen
the other types. In my opinion at the time I thought
of em as directional dipoles thinking they could be
turned by just turning a switch. I noticed on one
antenna there were coaxial cables that were about 2 or
3 inches in diameter.

From: charles allison
Topic: 1316 Message: 1316

There is a design for an antenna called the super loop. I believe Dr Ace's website talks about it a bit. It's an 80 meter horizontal delta with a 1/4 wavelength at 40meters twinline going through the middle. Has anyone made or tried this antenna, especially as an nvis mode?

best regards,

Charles

1318. NVIS Loop Skywire

Yahoo group: SkyWires
Date: 2005-09-30 12:44:05 UTC
From: Kyle
Topic: 1318 Message: 1318

Hello, please allow me to introduce myself. My name is Kyle. I am an electrical engineer with no formal training in RF, and I am a tech class operator. My wife and I are studying to upgrade to General (including learning the code). Right now we do all our hamming on 2m and are very disappointed with VHF propagation.

The bulk of what we want to do is between 0-100 miles, which puts us solidly in the HF skip zone. This makes NVIS (cloud warming) very attractive.

I plan to put up a Loop Skywire for our 80m NVIS needs, but it looks like I might also be able to have some occasional fun DXing on 20m. Wonderful!

I have read many articles on the Loop Skywire, but authors always seem to assume one has a flat piece of land. Well I am in the tip-toes of the foothills of the US Appalachian Mountains. My QTH is basically at the highest point in my county, which seems like it will help on all forms of communication. But my land is NOT flat. The house is on the peak of my property. Looking out of my back window it goes down hill, about 30' to a 1/4 acre pond, and then back up to house level at the back of my property.

I know experimenting is at the heart of ham radio. But I'd like to avoid unnecessary woes if at all possible. What might I expect from my skywire if I stay closer to the house and put the antenna over the down slope? Should the antenna slope with the land, or should it stay level and be higher from the ground on the back side?

I had thought about running it around the pond at the lower altitude, but I think that might mess up my 20m DX, and I don't want to be looking down on my antenna from the house. That just seems dumb to me (but what do I know?).

I had also thought about making the skywire 160m long and going all the way around the property, but I have read about a phenomenon of 2 wavelengths on 80m turning the lobes away from 90 degrees and degrading NVIS.

I am open to any and all suggestions. Hoping to turn the clouds orange in North GA soon!

-Kyle

1319. Re: [SkyWires] NVIS Loop Skywire

Yahoo group: SkyWires
Date: 2005-09-30 16:30:44 UTC
From: Gordon McCleery
Topic: 1318 Message: 1319

Kyle, my 5 year experiences with a 1000' loop up from 20' - 35' on sloping land in N. Florida, near the Ga. border (Monticello) are that I get great signal reports on 40 and 80, while I can work any station I can hear on the higher frequencies.
17 and 20 meters being my favorites, just because they are.
My antenna seems to give me high take off angles on 80 and 40 while lowering that take off angle on 14 mhz and up.
I am able to use this 1000' loop on six meters with a tuner and it also well there.
Upon occasion the loop appears to have less atmospheric
noise than a resonant 80 meter dipole at 85 feet off of
my tower. But also seems to get better reports than the
dipole.
If I run power, I have two amps I most often run an Icom 2kl at 400-500 watts out, more often than not run with the exciter an Icom 765 at 100 watts.
I run about 12 feet of good quality RG-213 to a 4:1 balun, under the eve of my home and then about 25 feet of commercial 450 Ohm ladder line to the loop.

Bottom line - try one you will like it, if your rig has an internal tuner, I am sure it will tune most if not all bands itself negating the need for an external tuner unless you plan to run an amp.

Good fortune with it let us all know how it works out for you.....73..Mac

I knew one ham in CT who had a 1400' loop on the side of a hill similar to what you describe. The wire ran through pulleys and was fed with open wire line. He would move the loop through the pulleys to change the directivity. Another friend in CT had his normal size loop supported by the trees circling his house.

Bigger is not always better. I found that by reducing the size of my loop from 1000' to 500' gave me a lobe instead of a small null toward the south east (eastern US seaboard) for a net that I call into ever week.

The best way is to model it using one of the available software programs. One you can try is eznec. Their website has a free demo program. www.eznec.com

1322. Re: NVIS Loop Skywire

Yahoo group: SkyWires
Date: 2005-10-05 05:07:43 UTC
From: nc9k
Topic: 1318 Message: 1322

Hello Kyle,

I am an RF electronics engineer. I have been experimenting with 2 12 ga. loop skywires, each at 35 ft. height. Each is fed with its own 450 ohm ladderline and Johnson KW matchbox, switched with a B&W Protax switch. Both are fed up to 1500W PEP on the bands where I use them. One loop is 40 meters long and the other is 160 meters long. The ladderline feed to the 40M loop is 75 feet long, while the feed to the 160M loop is 45 feet long.

The 40M loop runs great 80M to 10M, and consistently gives 2 S meter units higher signal strength readings on 80M up to 500 miles out, and past that point the 160M loop gives much stronger readings. At 40M through 10M which one provides stronger signal levels depends on ionospheric conditions. The 160M loop is consistently a European DX monster on 17M. With the sunspot cycle being the way it is, on 20M I find I am using both back and forth via the Protax switch. The 160M loop gives very good coverage on 160M. I have operated the 40M loop on 160M via my homemade link coupler, but I do not recommend this mode at any power above 100W because of the extreme RF voltage on the link coupler output. I would not try feeding the 40M loop 1500W PEP on 80M with anything but a Johnson KW matchbox, other "tuners" would vaporize with the internal voltages involved with that combo.

As far as loop tilt angles are concerned, you might notice a slight skewing in your vertical angle of radiation. Being H field magnetic antennas, the pond should make no difference to your loop operation.

73's and good luck,

Leland NC9K

From Ace, WH2T

Hi Charles,
I have been corresponding with Don, K8THU . He recently built the super loop antenna. Don gave me his permission to publish his comments. I intend to add them to the web page soon. I am waiting for any new info from Don.
Here is what Don, K8THU had to say about the Super Loop antenna.

Oct 17, 2005
Hi Ace,

Here is the update. My last antenna was a 80 meter full wave loop with about 260 feet in the shape of (roughly) a square. I could always load on 75, sometimes on 40 and rarely on 15. I tried it with a 4:1 balun and without. Same results.

Yesterday I made the superloop to your specs and hoisted it. Unfortunately the bottom 4 feet of the loop ended up on my roof. So I pulled up the bottom with the balun and the ladder line and raised that to become a completely horizontal triangle. It is up about 45 or 50 feet. My Kenwood 570 immediately loaded up on 75, 40, 20, 17, 15, and 12 but not 10. I will send you pics when I get a chance. Now I will wait to see how it performs.

I could with some effort get it up higher so it would clear the roof and be both vertical and horizontal if your research indicates that would be significantly better. I think the reason I couldn't load with the 80 meter loop is because of the limited range of my internal tuner.
But your specs work!

73,
Don, K8THU

Oct 18, 2005
Ace,
I just worked F5PFP near Lyons, France on 20 meters with the superloop.

Don,K8THU

Oct, 23 2005
Hi Ace,

Yesterday I had a fellow ham come over with his antenna analyzer. He found my resonant frequency was about 7.4 Mhz for 40 and also above 4.0 on 75. 20 was ok but not great (yet I worked France). 15 was bad. 10 was worse.
Next weekend I intend to tweak the length.
Don, K8THU

I will update the Super Loop antenna page as I get more info.
Ace - WH2T

Topic: 1326 Message: 1326

Just wanted to say hi to all on the group and tell you all that I've been a Delta Loop user for years. I have a full wave delta loop up for 80 meters and plan to put up a 160 full wave next spring.
My main radio is an Icom IC-706MKIIG with an IC-740 as a backup rig. Also use an IC-2720 dual bander for my vhf/uhf needs in the shack. I've had great luck with the full wave delta loop, along with the 706MKIIG with the AT-180 tuner. The AT-180 auto tuner tunes the delta loop from the low part of the 80 meter band right up to the top fo the 6 meter band. So needless to say this antenna fits my needs and I have a lot of natural antenna support structures, aka big red cedar trees to choise from. Between the cedar and douglas fir trees I have no need for any man made antenna structures, hi, hi. But then I live on Vancouver Island and I don't mind the rain as I don't have to shovel it in the winter.
Even though I live in a sort of a dip or small valley on the side of a mountain ridge and my closest neighbouring fellow ham lives about 1/4 of a mile from me. Would you believe that my loop is actually lower than his basement and it out preforms everyone for about a 100 mile radious of me.
I have to tell you about my property, the XYL and I are both amateurs and when we went looking for a parcel of land to build on, good radio reception was the most important criteria. Of course no covanets prohibiting antennas and no neighbours with pig or chicken farms with in 10 miles, hi hi.
We lucked out when we found the 2 acres we have, we drove onto the property and made contact with a station in Moscow, Japan and Scotland, so that did it for us. We went back to the realitor and made an rediculously low offer and the owner took it surprisingly. And here we are 14 years later still making contacts from the underground loop.

73.. for now ve7agw,
Al Winney,

Hi

Don't know if this is realivant to your "Supper Loop" or not, but my fullwave delta loop for 80 meters is 286 feet erected in a diamond. Also it's erected with the top point being about 70 feet high and the bottome point is about 40 feet, it's feed at one of the corners on the sides with 300 ohm. Then down to a remote 4:1 balun then coax about 20 feet to the AT-180 tuner.
With this configuration I checked the antenna with a anylizer and it resonates at 3730 with a 1.1:1 . Also works great all the way up to the top end of 6 meters with the tuner. Without the tuner it works great at 3730 of course and about center on 40 meters and similar on 20, 17, 15 and all of 10 meters. Before I added the balun the antenna had a very narrow band width. the balun is home made, with a binocular torrid and #14 solid copper wire. I've been using this configuration now for about 3 years and it preforms great. It seems

to be giving me the best of both vertical and horizontal benefits and keeps my noise level almost nonexistant. But then living in a rural area helps as well.

Welcome to the group, Al. I am new myself. In addition to what Terry asked, I'd also like to know two things:
1) how high off the ground at your qth is your antenna?
2) if your loop is horizontal, and the ground under your loop isn't level, does your loop slope with (parallel to) the ground or did you make it more or less level?

73s,
Kyle

From: ve7agw
Topic: 1326 Message: 1330

Hi Terry and the group,
My Delta Loop is actually about a 40 degree angel so I get the best
of both worlds, vertical and horizontal. When I first erected it I had it
pretty well plat horizontal and I didn't like the noise and the angle of
radiation I got. So I reconfigured it at a couple of different angles and
finally settled on approximately 40-41 degrees. It seems to perform at it's
best at this angle. I've made contacts in Europe, Australia, Japan, even
worked Africa in the afternoon on 75 meters about 4 days ago. I couldn't
believe my ears when I made contact, mind you it had a lot to do with the
band conditions. I also have a Mosely TA-33jr tri-bander at the 70 foot
level and it pretty well works all the upper band globally with no problems
at all.
I wanted to erect the 160 meter Delta Loop this year but it just
wasn't in the schedule so it didn't happen. There are a number of operators
on the BC Net on 3727 who use four square loops and full wave delta loops as
well with terrific results. The loop is a great antenna if you have the room
and the trees to erect it on. I wouldn't use any other type of antenna now.
In fact our club is planning on erecting a horizontal four square full wave
80 meter loop for our Emergency Operations Center for town's Provincial
Emergency Program (PEP).

73 for now, VE7AGW
Al

1331. New to the group

Yahoo group: SkyWires
Date: 2005-11-01 16:49:26 UTC
From: ve7agw
Topic: 1326 Message: 1331

Hi Kyle and the group,

To answer your question Kyle, the loop is at about a 40-41 degree slop in a diamond configuration. The highest point is about 70 feet above ground with the lowest point at approx. 40 ft above ground with spread distance in the middle points at approx. 60 feet. The ground slops up at the highest end but the antenna is actually at the 70 ft level above the ground even though the ground slops upward at this point.
The ground rises about 8 feet at the high end compared to the level point which is about the middle of the antenna.
I found that angling the antenna between 35-45 degrees cuts down the noise level considerable and it also gives you a far better angel of radiation from the antenna.
Completely horizontal loops or dipoles tend to have a high angle of radiation, where verticals have a very low angle. The loop dents to give you a high angle unless you angle it about 35-48 degrees. After playing with my loop for the last three years I've also found that changing the feed point has some positive effects as well. The feed point can change the impedance of the antenna drastically and give you a false vswr reading, specially if your using an auto tuner.

Hope this helps you, if you have any more questions ask and I'll do my best to answer them.

73...de ve7agw,
Al

I got another update on the "Super Loop" from Don - K8THU .
Here it is !

Hi Ace,
Ok on Saturday we removed the 1/4 wave stub and found it was about 30 inches too short so we changed it and pruned until it was resonant at 7.25. Then we reassembled the whole antenna and found with the extra stub length it was now resonant overall at 7.21 so I left it there for now and began SWR testing. Results follow:
3.995 1.1
3.751 2 to 1
7.164 1.1 to 1
7.290 1.2 to 1
14.151 1.3 to 1
14.348 1.7 to 1
21.250 2 to 1
21.441 2.5 to 1
24.932 3.5 to 1
24.987 can't load
28.331 3 to 1
29.650 can't load

Don, K8THU

Then down to a remote 4:1 balun then coax about 20 feet to the AT-180 tuner.
With this configuration I checked the antenna with a anylizer and it resonates at 3730 with a 1.1:1 . Also works great all the way up to the top end of 6 meters with the tuner. Without the tuner it works great at 3730 of course and about center on 40 meters and similar on 20, 17, 15 and all of 10 meters. Before I added the balun the antenna had a very narrow band width. the balun is home made, with a binocular torrid and #14 solid copper wire. I've been using this configuration now for about 3 years and it preforms great. It seems to be giving me the best of both vertical and horizontal benefits and keeps my noise level almost nonexistant. But then living in a rural area helps as well.

Hi Ace,

What's the size of the Super Loop ? It sounds like a winner if one has
the space.

1335. 1100 foot loop? New member

Yahoo group: SkyWires
Date: 2005-11-09 23:40:52 UTC
From: hrd998cc
Topic: 1335 Message: 1335

Hello all, I just found this group while researching loop antennas. I live on top of 10 steeply sloping acres with a few oak trees to hang wires from. By pacing the route from the house to the multiple trees, I figure I have room to hang about 1100 feet of loop. The loop would somewhat resemble home plate with my shack located at the V end. The goal is to have an antenna that will resonate, or at least tune up on the HF bands, 160 through 10 meters. I could cut it for one band, say 160 meters, but radiating on others is desirable as well.

Does anyone have any recommendations on where to start? I would like to avoid just blindly hanging up a random length of wire and bugging it out with an analyzer, but that is an option.

By the way, I must contend with CC&R's and antenna restrictions which pretty much limits my installations to wire antennas.

Thanks.

Russ

I think you've found the right group, Russ.

I also think that the ratio of trouble vs performance of an 1100 foot loop would make me shy away, even if I had the space. You see, I live in the 'burbs. I have a 60 x 110 foot plot. I have a 40m loop (140' around, also shaped something like home plate.) And I use 20 gauge insulated wire (longer loops usually need something heavier to deal with the tensile requirement.)

And my little pedestrian 40m loop gets out like, well, all get-out! Mine runs without a tuner on 40 and 160, then tunes easily with an outboard tuner for 20, 15, and 10. I have fossilized 1970's gear, so don't have the WARC bands... but I don't doubt that it would tune up there as well.

My recommendation - if you're not running more than a few hundred watts - is to use twinlead or window line... avoid coax if you can. Mine is run with regular TV twinlead, which - for the price - is a pretty darn good transmission line value. The stock formula for length is 1005 divided by frequency in MHz to get the length around. Select a configuration that encloses the greatest volume (circle is best, but in practice all sorts of other shapes work fine.) There's all sorts of construction tips in the group archives... floating insulators, using slingshots to get the pull lines high in trees. My all time favorite: the guy in Canada who got tired of looking for sinkers he shot over tree limbs in the woods - so he dipped them in gravy and let his dog find them for him.

My loop is about 18 feet high, and recently I worked Italy on 40m CW using about 5 watts output.

Best of luck to you...

Topic: 1335 Message: 1337

My loop is 980' works well on all bands with 100 watts. I have had no trouble with it here in northern Canada. Made with #12 insulated stranded wire, feed with 450ohm ladder line. I love the thing and all most never use my tribander any more, or my G5RV.
Just my 2 cents worth VE5HKC

1338. 1100 foot loop? New member

Yahoo group: SkyWires
Date: 2005-11-10 14:20:54 UTC
From: ve7agw
Topic: 1335 Message: 1338

Welcome to the group Russ,

I'm also a new member and if you want info on loops this is the place to look. I've been using a full wave delta loop in a diamond shape for about three, going on four years now. It's about 280' long and will load up flat on 80, 40, & 20 meters. I also have a 160 meter full wave loop ready to go up in the spring. Both antennas are fed with 300 ohm cheap TV wire down to just outside the window to the shack to a remote 4:1 home brew balun (5kw). Been using this configuration now for about three years and it out performs my Mosley TR-33 on 20 meters other than sign:noise ratio in pill ups I don't even use the TR-33 very often at all.
My plan is to erect the 160 meter in the spring and I expect it will perform about the same as the 80 meter. If you want to keep your antenna stealth then use "SuppaFlex" 12 to 14 gauge and hang it with black polypropylene 3/16" rope. And unless you know the antenna is there it will be very stealthy.
Fortunately for me, I live in the rural area of Vancouver Island and I can put up any antenna I want to pay for. Being a two amateur family makes the investment into equipment a budget item instead of a hit and seek one, hi, hi.

do you have a tuner with a 4 to 1 balun to tune the loop ? if so,
it should tune on all bands just fine....

1340. 160 meter loop

Yahoo group: SkyWires
Date: 2005-11-13 00:56:29 UTC
From: Skip Prinsen W1NNI
Topic: 1340 Message: 1340

I currently live in San Diego county and have a full wave loop up at about 25 - 30 feet. My wife and I are in the process of moving to the family farm in North Central Wyoming early next year. We will have 3 arces and more if it is needed for antennas. I would like to put up a multiple wave length loop at 50 feet next summer.

The present loop loads up on most of the bands with the bulit in tuner in the IC-756 Pro II. Does anyone have any suggestions as far as the length. I too have an analyizer and that is how I tuned the present one.

Thanks for any inputs.

73 de "Skip" W1NNI

Skip,
I agree with Bob.
Why mess with success. I also use a full wave loop.
Mine is cut for 75 meters and it's 272 feet of wire.

Subject: [SkyWires] 160 meter loop

I currently live in San Diego county and have a full wave loop up at about 25 - 30 feet. My wife and I are in the process of moving to the family farm in North Central Wyoming early next year. We will have 3 arces and more if it is needed for antennas. I would like to put up a multiple wave length loop at 50 feet next summer.

The present loop loads up on most of the bands with the bulit in tuner in the IC-756 Pro II. Does anyone have any suggestions as far as the length. I too have an analyizer and that is how I tuned the present one.

Thanks for any inputs.

remember too.....the bigger you make a loop antenna....the more major the lobes will be and you will have
poor coverage in areas far out on both transmit and recieve in many areas around the compass.....

Hi,
Here's my 2 cents.

After living on small city lots all of my adult life (other than during my military service) in 1994 I moved here to this rural mini farm and decided to experiment with some larger antennas since I now have the space. I am a rag chewer and very seldom attempt to work DX on the 160 or 75/80 meter bands.

The first antenna I made was a 1 wavelength 160 meter horizontal loop, then a 2 wavelength 160 meter loop, and then a 3 wavelength 160 meter loop antennas. I never intend to again put up any loop antenna larger than 530 feet of wire for 160 meters. I have experimented on other frequencies with up to a 10 wavelength loop antenna. As far as I could tell, the 1 wavelength 160 meter loop worked as well as if not better than the 3 wavelength 160 meter loop antenna. And I liked the way the 1 wavelength 160 meter loop performed better than the 2 wavelength 160 meter loop.

Later I built a 1 wavelength 80 meter delta shaped horizontal loop coax fed antenna that uses a 75 ohm coax Q section in the feedline. It works better than any of the 1, 2, or 3 wavelength 160 meter loop antennas on the 80 meter band. But as I said before I am a rag chewer and very seldom attempt to work DX on the 160 or 75/80 meter bands.

I now use a 1 wavelength 80 meter delta shaped horizontal loop antenna and a 160 meter band 1/4 wave inverted L "vertical" wire antenna. Two loops are more than I want to maintain. If I could only have one HF/MF antenna it would be a 1 wavelength 160 meter horizontal loop !

1345. BIGGER is not always BETTER...

Yahoo group: SkyWires
Date: 2005-11-14 03:49:36 UTC
From: Mike Schwendeman
Topic: 1345 Message: 1345

I agree with the two chaps below; I had VERY large loops erected,
and after finally listening to the advice from those who had "been
there," I went to a 540 foot square loop, up 45 to 50 feet. I feed this
with about 50 feet of 450 Ohm ladder line to an Icom AH-4 auto antenna
tuner. (I had 12 feet of RG-8 between the radio/antenna switch inside
the house and the auto tuner.)
My largest loop was in the area of 1900 feet of #14 wire. Overall,
the larger loop antennas were simply not that great! After trimming my
largest "grand experiment" to 540 feet, I now have a GOOD antenna.
(BIGGER is not always BETTER!) Operationally, the "shorter" loop is
much better in all cases, I believe. (Both for local and for DX.)
I also erected a 253 foot vertically polarized delta loop, fed with
50 feet of 450 Ohm ladder line at a lower corner. (The delta loop was
supported at the 105 foot level of my tower; The two bottom corners
were at about the 40 foot level, so the antenna had a very good chance
to "prove" itself.)
The feed lines for the 540 foot horizontal loop and the delta loop
were remotely "selected" by a heavy duty relay in my garage. The
selected antenna was then attached to the AH-4 auto tuner, so I could
almost "dynamically" choose and compare. I found that 90+ percent of
the time, the horizontal loop won both for local as well for DX on all
bands from 80 to 17 meters. I took the delta loop down, and carefully
coiled it and the fed line for storage. (Maybe some day...)
I will also add that I used a common home brew 75/40 meter dipole
at the 35 foot level as my REFERENCE ANTENNA to compare with the larger
antennas that I had. I found this to be an eye opener as I tried out
the wires that I had struggled to get into the air! (See the comments
below; These seem to agree with my outcome.)

I also had the idea that bigger was better with a 1000 foot loop up 30 to 50 feet and fed with balanced line. When I ran it through EZNEC I found a couple of nulls in directions where I wanted signal! Modeling a 540 foot version actually removed the nulls and gave slight gains in those areas. Reducing the loop to 500 from 540 feet gave no real difference according to the software so the old one came down, several new lines were installed over convenient trees, and the smaller loop went up.
